Analysis Approach

We fit ordinary least square linear regression models with robust standard errors in R (Version 4.3.0; R Core Team, 2024)) using the HC3 method in the *sandwich* package (Version 3.0.2; Zeileis, 2004; Zeileis, Köll, & Graham, 2004). For mediation analyses, we used the *mediation* package (Version 4.5.0; Tingley et al., 2014)) and *lavaan* (Version 0.6.16; Rosseel, 2012). For equivalence testing, we used the *TOSTER* package (Version 0.7.1; Caldwell, 2022, Lakens, 2017).

Creating the candidate pool

In order to run our experiments, we first collected a candidate pool. Our aim was to simulate real-world environments in which: 1) men are slightly advantaged in terms of past objective performance (whether because of bias or gender segregation in the labor market) and 2) gender diverse teams outperform homogeneous teams – they are less over-confident (Keck & Tang, 2018), higher performance (Hoogendoorn, Oosterbeek, & Van Praag, 2013), and are perceived as more creative (Proudfoot et al., 2023).

Method

Participants. We recruited 50 participants on Prolific and paid them \$3.00 to complete a 20-minute survey (25 women, 25 men; $M_{\text{age}}=40.46$ years, $SD=12.95$; 36 self-identified as mono-racial white). Each participant earned a bonus based on their performance across three games (bonuses could range from \$0-\$3.00).

Procedure. We first asked participants to provide us with a name or pseudonym. Then, we told them that they would play three different games to earn a bonus payment.

We described the three games that they would play: the Math Game, Angles Game, and Trivia Game. Participants played two ten-question rounds of each game, for a total of twenty questions for each game and sixty questions across all games. For each of those sixty questions, we allowed participants seven seconds to answer the question before the page automatically advanced. Each time they answered a question correctly, they earned \$0.05, so participants could earn up to \$3.00 in bonus payments by playing the games successfully. For example, trials of the games below, please see the Materials section.

The Math Game involved trials of a mental rotation task (Ganis & Kievit, 2015). We provided participants with pictures of two objects presented at different angles and their goal was to determine whether these two objects were the same or different.

The Angles Game included trials from the Judgment of Line Angle and Position Task (Collaer, Reimers, & Manning, 2007). Participants viewed a line and, below it, a set of 15 lines with corresponding numbers. They were asked to identify which line in the set matched the angle of the single line.

The Trivia Game required participants to answer multiple choice trivia questions. The trivia categories included: beauty, fashion, entertainment, and baking. We did not label questions by category for participants.

Finally, all participants answered questions about their demographics including age, gender, race, education, occupation, home state, and previous experience playing these kinds of games.

Results and Discussion

On average, across all games, men answered more questions correctly ($M=39.00$, $SD=6.78$) than women ($M=37.16$, $SD=9.84$), though this difference was not significant ($p=0.446$). Men performed marginally better on the Math Game ($M=16.76$, $SD=3.02$; $p=0.064$)

and significantly better on the Angles Game ($M=14.44$, $SD=3.88$; $p=0.001$) than women (Math Game: $M=14.84$, $SD=4.07$; Angles Game: $M=10.24$, $SD=4.67$). In contrast, women performed significantly better on the Trivia Game ($M=12.08$, $SD=4.09$) than men ($M=7.80$, $SD=2.31$), $p<0.001$. See Table S2 for more information.

We ran simulations to examine matchups between two randomly drawn 3-person teams: an all-male team vs. a gender-diverse team consisting of two men and one woman. Team scores were calculated by summing the scores of the highest scorer of each game. The team with the highest score was marked as winning the matchup. For teams that tied, we randomly chose whether the gender-diverse team or all-male team was marked as “winning.” with tie scores evenly split to each type of team. Across 10,000 simulated matchups, the gender-diverse team won 65.4% of the time whereas the all-male team won 34.6% of the time. Based on these simulations, we know that, on average, there is a benefit to creating a team consisting of two men and one woman as opposed to a team of three men.

Pilots to estimate sample size

Shortlist Stage Pilot

We recruited 175 U.S. adult participants on Prolific and paid them each \$1.50 to complete a 10-minute survey. Participants were randomly assigned to one of two conditions with unequal probability: *shortlist quota condition* (with $\frac{2}{3}$ probability; $n=124$) and *control condition* (with $\frac{1}{3}$ probability; $n=51$).

We conducted a Monte Carlo power analysis ($\alpha=0.05$) with 1,000 replications to determine whether a sample size of 1,500 was appropriately powered. Results indicated that with 1,500 participants, we would have 99.5% power to detect our effect ($b_ShortlistQuota=0.185$).

Hiring Stage Pilot

We recruited 175 U.S. adult participants on Prolific and paid them each \$1.50 to complete a 10-minute survey. Participants were randomly assigned to one of three conditions: *quota hidden condition* ($n=62$), *quota transparent condition* ($n=62$), and *control condition* ($n=51$).

We conducted a Monte Carlo power analysis ($\alpha=0.01$) with 1,000 replications to determine whether a sample size of 1,500 was appropriately powered to detect our smallest effect of interest. Results indicated that with 1,500 participants, we would have 91.10% power to detect our effect ($b_QuotaHidden=0.123$).

Summary Table of Experiments

Table S1. Summary of Experiments

Exp. #	Summary	Stages	Shortlist source	Conditions	Contribution
Main Experiments					
1a	Tests effect of shortlist quotas on # women <i>shortlisted</i> , and potential mediators (reactance, perceived unfairness, perceived norms, and perceived diversity values).	Shortlist Stage Only	-	Quota: 1,000 Control: 500	Tests Hypothesis 1
1b	Tests effect of shortlist quotas on # women <i>hired</i> . Also separately tests for implementation effects (via the <i>quota hidden</i> condition, implemented without decision-maker awareness) and communication effects (via the <i>quota transparent</i> condition, implemented with decision-maker awareness). Finally, tests mediators of the communication effect.	Hiring Stage Only	Shortlists from paired Exp. 1a participants	QuotaTransparent: 500 QuotaHidden: 500 Control: 500	Tests Hypotheses 2, 3a-b, 4a-b
2a	Tests the effect of shortlist quotas (on # women shortlisted and hired) when the same decision-maker shortlists and makes final hiring choices. Also tests our mediators.	Both Shortlist and Hiring Stages	Self-generated (since participants make both shortlisting and hiring decisions).	Quota: 1,000 Control: 500	Tests robustness of overall quota effect on hiring decisions when the same decision-maker both shortlists and hires candidates.
2b	Replicates Exp. 1b using shortlists generated in Exp. 2a. Allows us to directly compare shortlist quota effects when the same decision-maker makes shortlisting and hiring decisions vs. when the process is split across two different decision-makers.	Hiring Stage Only	Shortlists from paired Exp. 2a participants	QuotaTransparent: 500 QuotaHidden: 500 Control: 500	Compares overall quota effect between both-stage decision makers and only hiring stage decision-makers. Replicates tests of hypotheses 2, 3a-b, 4a-b
Supplementary Experiments					
S1a	Replicates Exp. 1a without mediators: tests effect of shortlist quotas on # women shortlisted	Shortlist Stage Only	-	Quota: 1,000 Control: 500	Replicates test of Hypothesis 1.

S1b	Replicates Exp. 1b without mediators: tests implementation and communication effects of shortlist quotas on hiring.	Hiring Stage Only	Shortlists from paired Exp. S1a participants	QuotaTransparent: 500 QuotaHidden: 500 Control: 500	Replicates test of Hypothesis 2.
S2a	Tests the effect of shortlist quotas on # women shortlisted with granular information provided on candidate performance. Also tests our mediators.	Shortlist Stage Only	-	Quota: 1,000 Control: 500	Tests robustness of Hypothesis 1 to settings with granular information about candidates.
S2b	Tests the effect of shortlist quotas on # women hired (and separately tests for implementation and communication effects) with granular information provided on candidate performance. Also tests our mediators.	Hiring Stage Only	Shortlists from paired Exp. S2a participants	QuotaTransparent: 500 QuotaHidden: 500 Control: 500	Tests robustness of Hypotheses 2, 3a-b, 4a-b to settings with granular information about candidates.

Supplementary Experiments: Design And Results

Experiment S1a: Shortlist Stage

In Experiment S1a, we aim to test Hypothesis 1 by identifying the impact of a shortlist quota on the number of women who are added to a shortlist in an incentive-compatible hiring paradigm. This is a direct replication of Experiment 1a in the manuscript, with the exception of measuring potential mediators; the procedures are otherwise identical to Experiment 1a.

Method

Participants. We recruited 1,500 U.S. adult participants on Prolific and paid them each \$1.50 to complete a 10-minute survey (740 women, 740 men, 18 non-binary, 2 another gender; $M_{age}=37.64$ years, $SD=13.15$; 1,058 self-identified as mono-racial white). Each participant could earn an additional \$1.00 (as a bonus) based on the performance of a team they helped create. The sample size was determined based on a pilot result and power analysis.

Procedure. Each participant reviewed a set of 10 “job candidates” for an open position on a team and then selected three finalists to advance in the hiring process. The open position that the participants’ decisions would help fill was a single slot on a team of three players (two players were already determined).

Each job candidate had completed an incentivized practice round playing three skill-based games: a math game, angles game, and trivia game (see Method Overview and Supplementary Materials for more details). Participants received descriptions of these games and information about overall job candidate performance on the practice games before selecting a set of three finalists from the 10 job candidates.

Participants knew that their candidate selection decisions would influence their eventual bonus payment because another Prolific worker would eventually choose one of the three finalists they selected to fill the open position on their team. Participants’ bonus payment would depend on their team’s performance in a new round of games. Specifically, each team formed would be randomly matched to compete against another real team in a second round of the same three games used for candidate screening (the math game, the angles game and the trivia game). The team with the highest overall score would win the matchup. Prolific workers would earn a \$1.00 bonus if their team won the matchup and would not earn a bonus if their team lost or tied. Participants completed a series of comprehension check questions to ensure that they understood this setup before proceeding to make actual selection decisions (see Supplementary Materials for details).

When making candidate selection decisions, participants viewed profiles of their team’s two existing team players. These existing team players were always men who had been randomly drawn from the available candidate pool. Profiles included a gendered avatar, pseudonym, the player’s gender, the player’s home state, and the player’s self-reported previous experience with games like the ones incentivized in this study.

In order to support the formation of stereotypes, we also informed participants about the average practice round game performance of the overall candidate pool (19.0/30) and several subgroups of players in the candidate pool: (1) women (19.0/30); (2) men (20.0/30); (3) candidates who self-reported that they were “not experienced at all” with the relevant types of games (17.0/30); and (4) candidates who self-reported that they were “moderately experienced” with the relevant types of games (17.5/30; see Supplementary Materials for more information). Participants were required to correctly answer comprehension check questions to ensure they were attending to the information presented before they were allowed to proceed.

Participants were randomly assigned to one of two conditions with unequal probability: the *shortlist quota condition* (with $\frac{2}{3}$ probability) or the *control condition* (with $\frac{1}{3}$ probability). In the *shortlist quota condition*, participants were told: “At least 1 of the 3 finalists you select must be a woman”. We enforced this requirement by prohibiting participants from moving forward unless their set of three finalists included at least one woman. In the *control condition*, participants’ only restriction was that their finalist set had to contain exactly three people.

When making selections, participants saw the profiles of ten job candidates (seven men and three women) drawn randomly from a pool of 50 real player profiles. Job candidate profiles included the same information as existing team member profiles. We opted to include a gender-imbalanced candidate pool to mirror natural environments where quota rules would be policy-relevant.

After participants chose three finalists to advance, they answered questions about their own demographics.

Results and Discussion

Fig. S1, Panel A. displays the distribution of women included in finalist sets by experimental condition. Following our pre-registered analysis plan, we ran a two-sample t-test comparing the number of women selected in participants’ finalist sets across conditions. As shown in Fig. S1, Panel A and consistent with Hypothesis 1, participants included significantly more women in the *shortlist quota condition* ($M=1.19$, $SD=0.44$) than the *control condition* ($M=0.72$, $SD=0.71$), $t(1498)=13.44$, $p<0.001$ (see Supplementary Materials for robustness checks and exploratory analyses regarding participant gender).

Notably, an exploratory two-sample proportions test revealed that participants in the *shortlist quota condition* created more finalist sets with more than one woman (16.8%) than participants in the *control condition* (11.6%), $\chi^2(1)=7.04$, $p=0.008$, which was primarily driven by a 4.9 pp. uptick in finalist sets containing two women in the *shortlist quota condition* (see Fig. S1, Panel A). If the shortlist quota operated purely mechanically by forcing participants to include one and only one woman in their finalist sets, we would expect to see an increase only in the number of finalist sets including one woman in the *shortlist quota condition*. Instead, we found that a significant number of our participants went beyond the minimum requirement of the shortlist quota, suggesting that shortlist quotas may also signal that gender diversity is valued or useful.

Fig. S1. The number of women included in finalist sets by Shortlist Stage participants across conditions.

(A) Experiment S1a (B) Experiment S2a

Experiment S1b: Hiring Stage

In Experiment S1b, we aimed to identify the implementation effects (Hypothesis 2) and communication effects (Hypotheses 3a and 4a) of shortlist quotas on the likelihood of a hiring manager actually hiring a woman in an incentive-compatible hiring paradigm. Participants in this experiment evaluated shortlists generated in Experiment S1a and made real hiring decisions. Those who evaluated quota-generated shortlists were randomly assigned to either learn about the quota, or not, allowing us to measure the communication effects of shortlist quotas over and above any implementation effects and adjudicate between Hypotheses 3a and 4a. This is a direct replication of Experiment 1b in the manuscript, without the inclusion of mediators: the procedures are otherwise identical to Experiment 1b.

Method

Participants. We recruited 1,500 participants on Prolific and paid them each \$1.50 to complete a 10-minute survey (775 women, 681 men, 39 non-binary; 5 another gender; $M_{\text{age}}=36.96$ years, $SD=14.13$; 1,097 self-identified as mono-racial white). Each participant could earn an additional \$1.00 (as a bonus) based on the performance of their team. The sample size was determined based on a pilot result and power analysis.

Procedure. Each participant selected a final team player from a shortlist of job candidates created by another Prolific worker (i.e., a participant in Experiment S1a). This final team player joined a team that already included two players. Participants were given the same information as Experiment S1a participants about the games job candidates were being hired to play, the practice rounds they had completed, and how bonus payments would be awarded. To ensure that participants understood this setup, we required that they correctly answer comprehension check questions before proceeding. As in Experiment S1a, participants saw profiles of their team's two existing (male) players and learned about the average performance of the same subgroups of job

candidates in practice games to support the formation of stereotypes. Again, participants were required to correctly answer comprehension check questions to proceed.

Participants were then randomly assigned to one of three conditions: the *quota transparent condition*, the *quota hidden condition*, or the *control condition*. In both *quota conditions*, participants evaluated a single set of three finalists for their team chosen by a single participant in the Experiment S1a *quota condition* (i.e., a finalist set created by a decision-maker who was forced to include at least one woman candidate). *Control condition* participants evaluated a single set of three finalists generated by Experiment S1a *control condition* participants. Each shortlist created in Experiment S1a was passed to exactly one participant in this experiment.

In the *quota transparent condition*, when participants were presented with finalist sets selected by a previous participant, they were (truthfully) told, “In an effort to offset a gender imbalance in the set of eligible players, this previous participant was required to include at least 1 woman in their finalist set.” In the *quota hidden condition*, participants were not given this information, so the language in the *quota hidden condition* and *control condition* was identical. After participants chose a single player from the three finalists to join their team, they answered questions about their own demographics.

Results and Discussion

Following our pre-registered analysis plan, we ran two ordinary least squares (OLS) regressions with robust standard errors to predict whether a given participant selected a woman to join their team (see Table S2). In the first regression shown in Table S2, Model 1, our primary predictor was an indicator for assignment to either of the *quota conditions*. We found that participants were significantly more likely to select a woman in the pooled *quota conditions* (25.5% selected a woman) than in the *control condition* (14.6% selected a woman; $p < 0.001$). In the second regression shown in Table S2, Model 2, our primary predictors were an indicator for assignment to the *quota transparent condition* and an indicator for assignment to the *quota hidden condition*. As shown in Fig. S2, Panel A, participants were significantly more likely to select a woman in the *quota hidden condition* (21.8% selected a woman) than in the *control condition* ($p = 0.003$), consistent with Hypothesis 2. Participants were also significantly more likely to select a woman in the *quota transparent condition* (29.2% selected a woman) than in the *control condition* (14.6% selected a woman; $p < 0.001$). A Wald test comparing the *quota transparent condition* and *quota hidden condition* revealed that participants were significantly more likely to select a woman (34% more women were hired) in the *quota transparent condition*, $p = 0.007$. Overall, these effects are consistent with Hypothesis 4a, which proposes positive communication effects of shortlist quotas, rather than Hypothesis 3a.

In order to further unpack the implementation effects vs. communication effects of the shortlist quota, we ran an exploratory OLS regression with robust standard errors to predict whether a given participant selected a woman to join their team including three primary predictors: an indicator for assignment to the *quota hidden condition*, an indicator for assignment

to the *quota transparent condition*, and a control for the number of women finalists shown to the participant (see Table S2, Model 3). This analysis allows us to quantify how the *quota transparent condition* impacts the number of women in the finalist set after holding constant the implementation effects of the number of women in the choice set. We found (unsurprisingly) that the number of women finalists presented to a participant significantly increased the likelihood of hiring a woman ($b_NumWomenFinalists=0.208$, $SE=0.018$, 95% CI [0.171, 0.244], $t(1496)=11.52$, $p<0.001$). Further, since the only difference between the *control condition* and *quota hidden condition* is the difference in how many women finalists are present at the hiring stage (as mandated by the shortlist quota), controlling for the number of women in the finalist sets eliminates any statistical difference between the *quota hidden condition* and the *control condition* ($b_QuotaHidden=-0.025$, $SE=0.026$, 95% CI [-0.077, 0.027], $t(1496)=-0.944$, $p=0.345$). After controlling for the number of women in the finalist set, however, we see a marginal increase in the likelihood participants hire a woman in the *quota transparent condition* compared to the *control condition* ($b_QuotaTransparent=0.049$, $SE=0.028$, 95% CI [-0.003, 0.100], $t(1496)=1.73$, $p=0.085$). We note however that our experimental design and pre-registered analysis comparing the outcomes of the *quota hidden* and *quota transparent* conditions are a cleaner and stronger test of the communication effects of the shortlist quota.

Taken together, we show that both transparent and hidden implementations of the shortlist quota were effective in increasing the likelihood that participants selected a woman at the final stage of the hiring process. We also demonstrate that transparent implementation of a shortlist quota further increased the likelihood of selecting a woman, compared with leaving individuals responsible for the final hiring decision unaware that job candidates had been vetted subject to this rule. In other words, we find that both the implementation and communication effects of shortlist quotas increase the likelihood that women are hired. These results are inconsistent with participants exhibiting reactance against shortlist quotas. Reactance should lead participants to be less likely to select a woman when they know about the imposition of a shortlist quota. Our results instead suggest that learning about the policy may have shifted participants' perceived value of hiring a woman.

Fig. S2. Likelihood of hiring a woman in Hiring Stage supplementary experiments across conditions.

Adjusted R²	0.015		0.019		0.094	

Note: This table shows the results of three ordinary least squares regressions. Model 1 predicts whether a woman was hired with an indicator for assignment to the pooled *quota conditions*. Model 2 predicts whether a woman was hired with separate indicators for assignment to the *quota transparent condition* and the *quota hidden condition*. Model 3 predicts whether a woman was hired with separate indicators for assignment to the *quota transparent condition* and the *quota hidden condition*, and a control for the number of women in the finalist set. Robust standard errors are presented in parentheses.

** $p < 0.01$, *** $p < 0.001$.

Experiment S2a

In Experiment S2a, we sought to replicate our results from Experiments 1a, testing whether a shortlist quota increases the number of women finalists selected at the Shortlist Stage (Hypothesis 1) in a context where decision-makers have granular information about candidates' individual past performance (i.e., practice round scores).

Method

Participants. We recruited 1,500 participants on Prolific and paid them each \$1.50 to complete a 10-minute online study (740 women, 745 men, 14 non-binary, 1 another gender; $M_{\text{age}} = 45.54$ years, $SD = 13.37$; 1065 self-identified as mono-racial white). 634 identify as Democrats, 447 as Republicans, and 419 as Independent. Each participant could earn an additional \$1.00 (as a bonus) based on the performance of a team they helped create.

Procedure. The procedure was identical to the procedure described in Experiment 1a with two exceptions. In addition to the candidate profile information we provided in previous experiments (i.e., a gendered avatar, pseudonym, the player's gender, the player's home state, and the player's self-reported previous experience with games like the ones incentivized in this study), we provided the following additional information: the player's practice round Math game score, the player's practice round Angles game score, and the player's practice round Trivia game score. We also provided additional information about the average performance across the candidate pool: average score in the practice Math game overall (7.9/10), average score in the practice Angles game overall (6.5/10), and average score in the practice Trivia game overall (4.8/10). Furthermore, participants had the option to click three buttons to learn more about (1) practice Math game performance (2) practice Angles game performance and (3) Trivia game performance, where we gave subgroup information about how women, men, players who reported being "Not experienced at all", and players who reported being "Moderately experienced" performed in each of these games.

We also collected an additional demographic measure: political orientation. We used the 7-point political ideology scale from the American National Election Studies (ANES, 2021). Participants responded to the prompt "When it comes to politics, do you usually think of yourself as...?" on a scale ranging from 1 (Extremely liberal) to 7 (Extremely conservative). See Materials in this Supplement for stimuli.

Results and Discussion

Following our pre-registered analysis plan, we ran a two-sample t-test comparing the number of women included in each participant's finalist set across conditions. As shown in Fig. S1, Panel B and replicating the results in Experiments 1a, 2a, and S1a, we found that participants included significantly more women in the *shortlist quota condition* ($M = 1.36$, $SD = 0.57$) than in the *control condition* ($M = 1.20$, $SD = 0.72$), $t(1498) = 4.367$, $p < 0.001$. However, we no longer find differences in *shortlist quota condition* participants' likelihood of going "above and beyond" the policy by shortlisting two or more women, $\text{difference} = -0.001$, $t(1498) = 0.039$, $p = 0.97$. While these results demonstrate that the shortlist quota increased the number of women shortlisted in the presence of more granular candidate information, the effect was smaller than in Experiments 1a, 2a and S1a. This might in-part represent a "ceiling effect": participants in the *control condition* were substantially more likely to include a woman in the shortlist than they were in Experiments 1a, 2a and S1a, and significantly more likely than chance. We explore this further below when discussing moderation by environment.

Mediation analyses predicting the number of women included in the finalists set. Next, we tested for evidence of our hypothesized mechanisms on the number of women included in the finalist set via mediation. Specifically, we tested each potential mediator (perceived norms, inferred organizational values, reactance, and perceived fairness) independently using a 10,000-sample bootstrapped mediation model, then tested each mechanism that yielded significant mediation in a 10,000-sample bootstrapped parallel mediation model.

We find evidence consistent with mediation by perceived norms and reactance: the bias-corrected 95% CIs for the size of the indirect effect of perceived norms (95% CI [0.013, 0.062]) and of reactance (95% CI [-0.017, -0.002]) both excluded zero. However, neither inferred organizational values nor perceived fairness significantly mediated the effect of the *shortlist quota condition* on selection decisions; although assignment to the *shortlist quota condition* increased inferred organizational values ($p < 0.001$) and decreased perceived fairness ($p < 0.001$), neither significantly predicted the number of women included in the finalist set (see Exploratory analyses for further details).¹

Given these results, we tested whether both perceived norms and reactance mediated the effect of the shortlist quota on the number of women included in the finalist set in a parallel mediation model. The results confirmed that perceived norms (*indirect effect* = 0.036, 95% CI [0.013, 0.060], $p = 0.003$) and reactance (*indirect effect* = -0.008, 95% CI [-0.017, -0.002], $p = 0.034$) significantly mediated the effect of shortlist quotas on the number of women included in the finalist set. See Robustness checks and exploratory analyses in this Supplement for exploratory mediation of the effect of the quota on selecting “two or more more women”.

Moderation by “female-dominated” vs. “male-dominated” environments. We next conducted exploratory analyses testing whether the effect of the shortlist quota was moderated by the relative qualifications of male and female candidates available for selection. We exploited the fact that the candidate pools of seven men and three women were randomly drawn from a set of fifty candidates for each participant, providing random variation in the relative qualifications (i.e., practice round scores) of women vs. men in candidate pools. Specifically, we calculated the expected average team score when randomly selecting a man vs. a woman as the final hire from each candidate pool. When selecting women would, on average, improve team scores relative to selecting men, we defined the candidate pool as “female-dominated”, and vice versa.

In male-dominated candidate pools, we found that participants included significantly more women in the *shortlist quota condition* ($M = 1.15$, $SD = 0.42$) than in the *control condition* ($M = 0.76$, $SD = 0.64$); $t(386) = 7.292$, $p < 0.001$. By contrast, in female-dominated pools, participants in the *shortlist quota condition* included only directionally more women in the shortlist ($M = 1.44$, $SD = 0.57$) than in the *control condition*, where the number of women shortlisted was already high ($M = 1.38$, $SD = 0.72$); $t(1100) = 1.57$, $p = 0.115$. Consistent with these results, the impact of the quota on the number of women shortlisted was significantly moderated

¹ Bias-corrected 95% CI for the size of the indirect effect of inferred organizational values (95% CI [-0.023, 0.005]) and perceived fairness (95% CI [-0.008, 0.004]) both included zero. See Robustness checks and exploratory analyses for more details.

by whether the environment was male- vs female-dominated, $b_{FemaleDominated \times Quota} = -0.334$, $SE = 0.075$, 95% CI $[-0.478, -0.190]$, $t(1496) = -4.469$, $p < 0.001$. See Robustness checks and exploratory analyses in this Supplement for all results of moderation by baseline qualifications.

Experiment S2b

In Experiment S2b, we sought to replicate our results from Experiments 1b, testing the implementation effects (Hypothesis 2) and communication effects (Hypotheses 3a and 4a) of shortlist quotas on the likelihood of hiring a woman in a context where decision-makers have granular information about candidates' individual past performance (i.e., practice round scores). Participants in this experiment evaluated shortlists generated in Experiment S2a and made real hiring decisions.

Method

Participants. We recruited 1,500 participants on Prolific and paid them each \$1.50 to play a 10-minute online game (758 women, 767 men, 21 non-binary, 2 another gender; $M_{age} = 43.43$ years, $SD = 14.41$; 1062 self-identified as mono-racial white). 651 identify as Democrats, 395 as Republicans, and 502 as Independent. Each participant could earn an additional \$1.00 (as a bonus) based on the performance of a team they helped create.

Procedure. The procedure was identical to the procedure described in Experiment 2b with two exceptions, similar to Experiment S2a. In addition to the candidate profile information we provided in previous experiments (i.e., a gendered avatar, pseudonym, the player's gender, the player's home state, and the player's self-reported previous experience with games like the ones incentivized in this study), we provided the following additional information: the player's practice round Math game score, the player's practice round Angles game score, and the player's practice round Trivia game score. We also provided additional information about the average performance across the candidate pool: average score in the practice Math game overall (7.9/10), average score in the practice Angles game overall (6.5/10), and average score in the practice Trivia game overall (4.8/10). Furthermore, participants had the option to click three buttons to learn more about (1) practice Math game performance (2) practice Angles game performance and (3) Trivia game performance, where we gave subgroup information about how women, men, players who reported being "Not experienced at all", and players who reported being "Moderately experienced" performed in each of these games. See Materials in this Supplement for stimuli.

Results

Likelihood of Hiring a Woman. Following our pre-registered analysis plan, we ran two ordinary least squares (OLS) regressions with robust standard errors to predict whether a participant selected a woman to join their team (see Table S3). In the first regression shown in Table S3, Model 1, our primary predictor was an indicator for assignment to either of the *quota conditions*. As in Experiments 1b, 2b and S1b, we found that participants were significantly

more likely to select a woman in the pooled *quota conditions* (66.7% selected a woman) than in the *control condition* (60.8% selected a woman; $p=0.026$).

In the second regression shown in Table S3, Model 2, our primary predictors were an indicator for assignment to the *quota transparent condition* and an indicator for assignment to the *quota hidden condition*. As shown in Fig. S2, Panel B, participants were again significantly more likely to select a woman in the *quota hidden condition* (67.6% selected a woman) than in the *control condition* ($p=0.025$), consistent with Hypothesis 2. In contrast to Experiments 1b, 2b, and S1b participants were not significantly more likely to select a woman in the *quota transparent condition* (65.8% selected a woman) than in the *control condition* ($p=0.101$). A Wald test comparing the *quota transparent condition* and *quota hidden condition* revealed that there was no significant difference in the likelihood of selecting a woman in the *quota transparent condition* ($p=0.547$).

As in Experiments 1b, 2b and S1b, we further explore the communication effects of shortlist quotas over and above their implementation effects by running an exploratory OLS regression predicting the final selection of a woman including three primary predictors: an indicator for assignment to the *quota hidden condition*, an indicator for assignment to the *quota transparent condition*, and a control for the number of women finalists (see Table S3, Model 3). We found a (mechanical) positive effect of the number of women finalists ($b_NumWomenFinalists=0.320$, $SE=0.013$, 95% CI [0.284, 0.355], $t(1496)=23.75$, $p<0.001$), and, as expected, controlling for these effects eliminated the difference between the *control condition* and *quota hidden condition* by shutting down the only channel through which these conditions differed ($b_QuotaHidden=0.015$, $SE=0.027$, 95% CI [-0.039, 0.069], $t(1496)=0.545$, $p=0.586$). In contrast to Experiment 1b, we do not observe a significant difference between the *control condition* and *quota transparent condition* ($b_QuotaTransparent=-0.002$, $SE=0.0028$, 95% CI [-0.057, 0.052], $t(1496)=-0.088$, $p=0.930$) after controlling for the number of female finalists under consideration.

Mediation Analyses. We explored potential mechanisms for the effects of transparent (vs. hidden) quotas on participants' willingness to hire a woman. Following our pre-registration, we first separately evaluated the effects of each of our hypothesized mediators using a 10,000-sample bootstrapped mediation model.

We found that the 95% bias-corrected confidence intervals for the indirect effect of perceived norms (95% CI [0.001, 0.028]) excluded zero suggesting that participants' perceptions of the normative pressure to select a woman partially account for the effect of transparent (vs. hidden) quotas on the likelihood of hiring a woman. These effects are consistent with Hypothesis 4b. However, inferred organizational values, reactance, and perceived fairness did not significantly mediate the relationship between transparently implemented quotas and participants' likelihood of hiring a woman; explicitly informing participants about the shortlist

quota did not inspire increased inferences of organizational values ($p=0.338$), more reactance ($p=0.812$) nor did it affect perceived fairness ($p=0.343$).²

Moderation by “female-dominated” vs “male-dominated” environments. As in Experiment S2a, we tested for moderation of the effects of shortlist quotas by the relative qualifications of men and women in the original candidate pools used to select the shortlists. As in Experiment S2a, we divided candidate pools into those that were “male-dominated” (where men were more qualified than women in the original candidate pool) vs. “female-dominated” (where women were more qualified). When pools were male-dominated, we found that participants were significantly more likely to select a woman in the pooled *quota conditions* (40.3% selected a woman) than in the *control condition* (27.9% selected a woman; $p=0.012$). However, when shortlists were generated from female-dominated pools, there was no statistical difference in the likelihood of hiring a woman across the pooled *quota condition* (75.8% selected a woman) vs. the *control condition* (73.6% selected a woman; $p=0.525$). We find directional (but non-significant) evidence of moderation of the effect of shortlist quotas on hiring women based on whether the original candidate pool was female-dominated, $b_FemaleDominated \times PooledQuota = -0.107$, $SE=0.055$, 95% CI [0.001, -0.215], $t(1496)=-1.94$, $p=0.053$.

We do not observe a significant difference between the *quota hidden condition* and the *quota transparent condition* in either male-dominated or female-dominated pools.³ See Robustness checks and exploratory analyses in this Supplement for the full details of these results.

Perceived Competence of Final Hires. Finally, in order to examine whether the perceived competence of final hires differed across conditions, we examined whether there were condition-based differences in participants’ forecasted overall score of their final hire. Equivalence tests using the two one-sided t-test (TOST) method (Lakens, 2017) comparing (1) *control condition* vs. pooled *quota conditions*, (2) *control condition* vs. *quota hidden condition*, (3) *control condition* vs. *quota transparent condition*, (4) *quota hidden condition* vs. *quota transparent condition*, show that the forecasted overall scores of hires are equivalent at 90% confidence, using a tolerance margin of ± 0.6 (see Supplementary Materials for further details). In sum, we did not find any evidence that individuals hired when the shortlist quota was in place were perceived as less competent by decision-makers.

Table S3. Ordinary least squared (OLS) regressions predicting whether a woman was hired in Experiment S2b.

Model 1		Model 2		Model 3	
Estimate	<i>p</i>	Estimate	<i>p</i>	Estimate	<i>p</i>

² Bias-corrected 95% CI for the size of the indirect effect of inferred organizational values (95% CI [-0.002, 0.002]) reactance (95% CI [-0.004, 0.006]) and perceived fairness (95% CI [-0.004, 0.001]) all included zero.

³ In male-dominated environments, the result of a Wald Test comparing the difference in likelihood of hiring a woman between the *quota hidden condition* and *quota transparent condition* revealed no difference ($p=0.356$). In female-dominated environments, the same test also revealed no difference ($p=0.609$).

Note: This table shows the results of three ordinary least squares regressions. Model 1 predicts whether a woman was hired with an indicator for assignment to the pooled *quota conditions*. Model 2 predicts whether a woman was hired with separate indicators for assignment to the *quota transparent condition* and the *quota hidden condition*. Model 3 predicts whether a woman was hired with separate indicators for assignment to the *quota transparent condition* and the *quota hidden condition*, and a control for the number of women in the finalist set. Robust standard errors are presented in parentheses.

** $p < 0.01$, *** $p < 0.001$.

Robustness checks and exploratory analyses

Across each of our experiments, we ran several pre-registered robustness checks to ensure that our results remained consistent when: (1) running Mann-Whitney U tests, (2) running OLS regressions with robust standard errors, controlling for participant gender, (3) running logistic regressions, and (4) running proportions tests, where relevant. For each experiment, we report the results of those robustness checks in this section. We also report more details of pre-registered analyses and the results of exploratory analyses, including an analysis of team quality across conditions in Experiment 1b and further details on our mediation analyses from Experiments 2a and 2b.

Experiment 1a

Robustness checks. We ran a Mann-Whitney U test ($U=152882$, $p<0.001$), OLS regression with robust standard errors ($b_ShortlistQuota=0.479$, $SE=0.035$, 95% CI [0.419, 0.539], $t(1498)=13.75$, $p<0.001$), and Poisson regression ($b_ShortlistQuota=0.505$, $SE=0.060$, 95% CI [0.389, 0.623], $z(1498)=8.45$, $p<0.001$) to compare the number of women included in participants' finalist sets across conditions and found similar results to those reported in our primary pre-registered analysis. Specifically, all robustness checks suggest more women are included in finalist teams in the *shortlist quota condition*. Our results are also robust to controlling for participant gender, $b_ShortlistQuota=0.483$, $SE=0.035$, 95% CI [0.423, 0.543], $t(1497)=13.95$, $p<0.001$, with participants who identify as men (as compared to women, non-binary, and other gender participants) less likely to select more women, $b_Men=-0.119$, $SE=0.029$, 95% CI [-0.176, -0.063], $t(1497)=-4.15$, $p<0.001$.

Pre-registered analysis: Mediation by perceived norms and inferred organizational values on the number of women included in the finalist set. We examine the effect of assignment to the *shortlist quota condition* on each of our four potential mediators (perceived norms, inferred organizational values, reactance, and perceived fairness), the correlation between each mediator and the number of women included in the finalist set, and the effect of condition assignment on women included in the finalist set with and without the mediator as a control. We then examine the results of pre-registered bootstrapped mediation analyses.

Mediation by perceived norms. First, there was a significant effect of assignment to the *shortlist quota condition* on perceived norms, $b_ShortlistQuota=0.860$, $SE=0.074$, 95% CI [0.717, 1.00], $t(1498)=11.66$, $p<0.001$. Second, the relationship between perceived norms and the number of women included in a finalist set was also significant, $b_Norms=0.128$, $SE=0.011$, 95% CI [0.107, 0.149], $t(1498)=11.64$, $p<0.001$. Consistent with partial mediation, the effect of assignment to the *shortlist quota condition* on the number of women included in a finalist set ($b_ShortlistQuota=0.479$, $SE=0.035$, 95% CI [0.419, 0.539], $t(1498)=13.75$, $p<0.001$) decreased when controlling for perceived norms ($b_ShortlistQuota=0.403$, $SE=0.034$, 95% CI [0.336, 0.464], $t(1497)=11.76$, $p<0.001$). A 10,000-sample bootstrap analysis confirmed that this reduction in effect size was significant, $b_reduction=0.077$, $p<0.001$, with a bias-corrected 95% CI for the size of the indirect effect that excluded zero (95% CI [0.056, 0.100]).

Mediation by inferred organizational values. There was a significant effect of assignment to the *shortlist quota condition* on alignment with inferred organizational values, $b_ShortlistQuota=0.503$, $SE=0.093$, 95% CI [0.320, 0.686], $t(1498)=5.42$, $p<0.001$. Second, the relationship between inferred organizational values and the number of women included in a finalist set was also significant, $b_OrgValues=0.068$, $SE=0.009$, 95% CI [0.051, 0.086], $t(1498)=7.59$, $p<0.001$. Consistent with partial mediation, the effect of assignment to the *shortlist quota condition* on the number of women included in a finalist set ($b_ShortlistQuota=0.479$, $SE=0.035$, 95% CI [0.419, 0.539], $t(1498)=13.75$, $p<0.001$) decreased when controlling for inferred organizational values ($b_ShortlistQuota=0.453$, $SE=0.034$, 95% CI [0.034, 0.067], $t(1497)=13.25$, $p<0.001$). A 10,000-sample bootstrap analysis confirmed that this reduction in effect size was significant, $b_reduction=0.026$, $p<0.001$ with a bias-corrected 95% CI for the size of the indirect effect that excluded zero (95% CI [0.014, 0.040]).

No mediation by reactance. There was a significant effect of assignment to the *shortlist quota condition* on reactance, $b_ShortlistQuota=0.187$, $SE=0.084$, 95% CI [0.020, 0.354], $t(1498)=2.24$, $p=0.025$. However, the relationship between reactance and the number of women included in a finalist set was not significant, $b_Reactance=0.001$, $SE=0.011$, 95% CI [-0.018, 0.021], $t(1498)=0.122$, $p=0.903$, and the bias-corrected 95% CI for the size of the indirect effect of reactance included zero (95% CI [-0.006, 0.000]). Thus, there was no evidence confirming that reactance mediates the effect of shortlist quotas on the number of women included in a finalist set.

No mediation by perceived fairness of the evaluation process. There was a significant effect of assignment to the *shortlist quota condition* on perceived fairness of the evaluation process, $b_ShortlistQuota=-0.199$, $SE=0.067$, 95% CI [-0.333, -0.064], $t(1498)=-2.97$, $p=0.003$. However, the relationship between perceived fairness and the number of women included in a finalist set was not significant, $b_Fairness=-0.021$, $SE=0.013$, 95% CI [-0.045, 0.003], $t(1498)=-1.63$, $p=0.104$, and the bias-corrected 95% CI for the size of the indirect effect of reactance included zero (95% CI [-0.003, 0.010]). Thus, there was no evidence confirming that perceived fairness mediates the effect of shortlist quotas on the number of women included in a finalist set.

Parallel mediation analysis with perceived norms and inferred organizational values. Given these results, we next tested whether both perceived norms and inferred organizational values would continue to mediate in a parallel mediation model, following our pre-registration. This parallel mediation model allows us to address potential multicollinearity between these correlated measures ($r=0.44$, $p<0.001$). The results confirmed that both perceived norms (*indirect effect*=0.064, 95% CI [0.043, 0.089], $p<0.001$) and inferred organizational values (*indirect effect*=0.013, 95% CI [0.004, 0.025], $p=0.012$) significantly mediated the effect of shortlist quotas on the number of women included in a finalist set.

Exploratory analyses. *Moderation by participant gender and race.* First, we explored the interaction between participant gender and the presence of a shortlist quota via an exploratory OLS regression with robust standard errors to predict the number of women selected. We find that the interaction between participant gender and assignment to the *shortlist quota condition* is

not significant ($b_ShortlistQuota-x-Men=0.115$, $SE=0.069$, 95% CI [-0.005, 0.235], $t(1496)=1.66$, $p=0.097$). Next, we explored moderation by participant race using the same exploratory regression procedure. We find that the interaction between participant race (the participant being “White”) and assignment to the *shortlist quota condition* is not significant ($b_ShortlistQuota-x-White=-0.121$, $SE=0.071$, 95% CI [-0.249, 0.007], $t(1496)=-1.70$, $p=0.089$).

Mediation analyses on selecting finalist sets with more than one woman. We examine the effect of assignment to the *shortlist quota condition* on each of our four potential mediators (perceived norms, inferred organizational values, reactance, and perceived fairness), the correlation between each mediator and the number of women included in the finalist set, and the effect of condition assignment on including more than one woman in the finalists set with and without the mediator as a control.

Mediation by perceived norms. The relationship between perceived norms and selecting more than one woman for the finalist set was also significant, $b_Norms=0.030$, $SE=0.006$, 95% CI [0.017, 0.044], $t(1498)=4.89$, $p<0.001$. Consistent with mediation, the effect of assignment to the *shortlist quota condition* on including more than one woman in a finalist set ($b_ShortlistQuota=0.052$, $SE=0.019$, 95% CI [0.012, 0.092], $t(1498)=2.70$, $p=0.007$) decreased when controlling for perceived norms ($b_ShortlistQuota=0.028$, $SE=0.020$, 95% CI [-0.013, 0.069], $t(1498)=1.41$, $p=0.159$). A 10,000-sample bootstrap analysis confirmed that this reduction in effect size was significant, $b_reduction=0.024$, $p<0.001$.

Mediation by perceived organizational values. The relationship between inferred organizational values and selecting more than one woman for the finalist set was also significant, $b_OrgValues=0.068$, $SE=0.009$, 95% CI [0.051, 0.086], $t(1498)=7.59$, $p<0.001$. Consistent with partial mediation, the effect of assignment to the *shortlist quota condition* on including more than one woman in a finalist set ($b_ShortlistQuota=0.052$, $SE=0.019$, 95% CI [0.012, 0.092], $t(1498)=2.70$, $p=0.007$) decreased when controlling for inferred organizational values ($b_ShortlistQuota=0.044$, $SE=0.020$, 95% CI [0.004, 0.084], $t(1498)=2.25$, $p=0.025$). A 10,000-sample bootstrap analysis confirmed that this reduction in effect size was significant, $b_reduction=0.008$, $p=0.005$.

Marginal mediation by reactance. There was a significant effect of assignment to the *shortlist quota condition* on reactance, $b_ShortlistQuota=0.187$, $SE=0.084$, 95% CI [0.020, 0.354], $t(1498)=2.24$, $p=0.025$. The relationship between reactance and including more than one woman in a finalist set was significant, $b_Reactance=-0.012$, $SE=0.006$, 95% CI [-0.024, -0.00001], $t(1498)=-2.07$, $p=0.038$, but the bias-corrected 95% CI for the size of the indirect effect of reactance included zero (95% CI [-0.006, 0.00001]), and the reduction in effect size was marginal, $b_reduction=-0.002$, $p=0.051$. Thus, there was marginal evidence that reactance mediates the effect of shortlist quotas on including more than one woman in a finalist set.

No mediation by perceived fairness of the evaluation process. There was a significant effect of assignment to the *shortlist quota condition* on perceived fairness of the evaluation process, $b_ShortlistQuota=-0.199$, $SE=0.067$, 95% CI [-0.333, -0.064], $t(1498)=-2.97$, $p=0.003$. However, the relationship between perceived fairness and including more than one woman in the

finalist set was not significant, $b_{Fairness}=-0.005$, $SE=0.008$, 95% CI [-0.020, 0.010], $t(1498)=-0.59$, $p=0.552$, and the bias-corrected 95% CI for the size of the indirect effect of perceived fairness included zero (95% CI [-0.003, 0.004]). Thus, there was no evidence confirming that perceived fairness mediates the effect of shortlist quotas on including more than one woman in the finalist set.

Parallel mediation with perceived norms and inferred organizational values. Given these results, we next tested whether both perceived norms and inferred organizational values would continue to mediate in a parallel mediation model. The results confirmed that perceived norms (*indirect effect*=0.020, 95% CI [0.008, 0.034], $p=0.003$) but not inferred organizational values (*indirect effect*=0.004, 95% CI [-0.002, 0.011], $p=0.212$) significantly mediated the effect of shortlist quotas on including more than one woman in a finalist set.

Experiment 1b

Robustness checks. We first examined our analyses predicting rates of hiring a woman with an indicator for assignment to the (pooled) *quota conditions*. Our OLS regression results from the main manuscript are robust to controlling for participant gender, $b_{QuotaPooled}=0.148$, $SE=0.021$, 95% CI [0.103, 0.193], $t(1497)=7.08$, $p<0.001$. We also find that participants who identify as men (as compared to women, non-binary, and other gender participants) are less likely to hire a woman, $b_{Men}=-0.076$, $SE=0.021$, 95% CI [-0.118, -0.034], $t(1497)=3.56$, $p<0.001$. Similarly, we replicate the results from our primary pre-registered analyses when we control for participant gender and include separate indicators for assignment to the *quota hidden condition*, $b_{QuotaHidden}=0.107$, $SE=0.025$, 95% CI [0.055, 0.159], $t(1496)=4.36$, $p<0.001$ and *quota transparent condition*, $b_{QuotaTransparent}=0.189$, $SE=0.026$, 95% CI [0.137, 0.240], $t(1496)=7.29$, $p<0.001$. Again, participants who identify as men are less likely to hire a woman, $b_{Men}=-0.074$, $SE=0.021$, 95% CI [-0.117, -0.032], $t(1496)=-3.48$, $p<0.001$.

We ran two-sample tests of proportions comparing the proportion of women hired in the *control condition* (13.6%) vs. the pooled *quota conditions* (28.4%), $\chi^2(1)=40.65$, $p<0.001$, 95% CI [-0.189, -0.107], and found similar results to our main analysis. We also compared the proportion of women hired in the *quota hidden condition* (24.2%) vs. *control condition* ($\chi^2(1)=18.33$, $p<0.001$, 95% CI [-0.154, -0.058]), *quota transparent condition* (32.6%) vs. *control condition* ($\chi^2(1)=50.81$, $p<0.001$, 95% CI [-0.241, -0.139]), and *quota hidden condition* vs. *quota transparent condition* ($\chi^2(1)=8.68$, $p=0.003$, 95% CI [-0.140, -0.028]), and found results consistent with those presented in the main text.

We also ran a logistic regression predicting the likelihood of hiring a woman as a function of assignment to the pooled *quota conditions*, $LO_{QuotaPooled}=0.924$, $SE=0.148$, $z=6.24$, $p<0.001$ and a logistic regression with indicators for the *quota hidden condition*, $LO_{QuotaHidden}=0.707$, $SE=0.167$, $z=4.23$, $p<0.001$ and *quota transparent condition*, $LO_{QuotaTransparent}=1.12$, $SE=0.162$, $z=6.95$, $p<0.001$. Again, the results of these robustness checks are consistent with our primary pre-registered analyses in the main text.

Pre-registered analyses. In pre-registered exploratory analyses, we examined the perceived competence of the final hire to assess whether shortlist quotas might have deleterious downstream consequences for women eventually hired to join a team.

Perceived competence of final hire. In order to examine whether participants' perceived competence of their final hire differed across conditions, we ran two ordinary least squares (OLS) regressions with robust standard errors to predict participants' forecasted overall score of their final hire. Similar to our main analysis, our primary predictor in the first regression was an indicator for assignment to either of the *quota conditions*. We found no significant difference in participants' forecasted overall scores of their hires across the pooled *quota conditions* and the *control condition* ($b_{PooledQuota}=0.102$, $SE=0.188$, 95% CI [-0.273, 0.478], $t(1498)=0.545$, $p=0.586$). Similarly, in the second regression, we found no significant difference in predicted overall scores between any of the three conditions (*control* vs. *quota transparent*, $b_{QuotaTransparent}=-0.004$, $SE=0.225$, 95% CI [-0.437, 0.429], $t(1497)=-0.018$, $p=0.986$; *control* vs. *quota hidden*, $b_{QuotaHidden}=0.209$, $SE=0.213$, 95% CI [-0.224, 0.642], $t(1497)=0.982$, $p=0.326$; *quota transparent* vs. *quota hidden*, $b_{QuotaTransparent}=-0.209$, $SE=0.225$, 95% CI [-0.646, 0.220], $t(1497)=-0.947$, $p=0.344$). Equivalence tests using the two one-sided t-test (TOST) method comparing 1) *control condition* vs. pooled *quota conditions*, 2) *control condition* vs. *quota hidden condition*, 3) *control condition* vs. *quota transparent condition*, 4) *quota hidden condition* vs. *quota transparent condition*, shows that the forecasted overall score of hires are equivalent at 90% confidence, using a tolerance margin of ± 0.6 .

Exploratory analyses. *Moderation by participant gender and race.* To assess whether participant gender impacted our results, we ran an exploratory OLS regression with robust standard errors to predict whether a given participant selected a woman to join their team. Our primary predictors were an indicator for assignment to the *quota transparent condition*, an indicator for assignment to the *quota hidden condition*, and a binary indicator for participant gender (man=1, woman, non-binary, or another gender=0), and the interaction between these indicators. We did not find significant interactions between participant gender and assignment to either experimental condition ($ps>0.05$). Next, we explored moderation by participant race using the same exploratory regression procedure and also did not find significant interactions between participant race (the participant being "White" or non-White) and assignment to either experimental condition ($ps>0.05$).

Next, to further explore the communication effects of shortlist quotas over and above their implementation effects, we ran an exploratory OLS regression predicting the final selection of a woman including three primary predictors: an indicator for assignment to the *quota hidden condition*, an indicator for assignment to the *quota transparent condition*, and a control for the number of women finalists. We found a (mechanical) positive effect of the number of women finalists ($b_{NumWomenFinalists}=0.202$, $SE=0.018$, 95% CI [0.166, 0.239], $t(1496)=11.51$, $p<0.001$), and, as expected, controlling for these effects eliminated the difference between the *control condition* and *quota hidden condition* by shutting down the only channel through which these conditions differed ($b_{QuotaHidden}=0.009$, $SE=0.027$, 95% CI [-0.044, 0.062],

$t(1496)=0.333, p=0.739$). However, we still observe a significant difference between the *control condition* and *quota transparent condition* ($b_QuotaTransparent=0.0893, SE=0.029, 95\% CI [0.041, 0.146], t(1496)=3.27, p=0.001$) even after controlling for the number of female finalists under consideration, such that women were more likely to be hired in the *quota transparent condition* than in the *control condition*. These results offer further evidence that shortlist quotas boost the selection of women not just mechanically, but also by signaling that gender diversity is supported.

Next, we explored potential mechanisms for the effects of transparent (vs. hidden) quotas. We do not find evidence of mediation by any of our hypothesized mechanisms of the effect of the (pooled) *quota conditions* vs. *control condition* or for the *quota hidden condition* vs. the *control condition*, so we do not report those mediation analyses in more depth. However, all analysis code to run those analyses is included in our OSF repository. Following our pre-registration, to examine whether perceived norms around hiring a woman, inferred organizational values, reactance, or perceived fairness of the evaluation process mediated the effect of the transparent vs. hidden shortlist quota on the likelihood of hiring a woman, we first examined whether there were condition-based differences for each potential mediator by running two OLS regressions with robust standard errors with forms identical to our main analysis. We first separately considered each of our hypothesized mediators and ran a mediation analysis using a 10,000-sample bootstrapped mediation model to explore for mediators that yielded condition-based differences. We then ran parallel mediation analyses for the significant mediators, as pre-registered, which are reported in the main text.

Mediation by perceived norms around hiring a woman. First, there was a significant effect of assignment to the *quota transparent condition* (compared to the *quota hidden condition*) on perceived norms, $b_QuotaTransparent=0.351, SE=0.076, 95\% CI [0.200, 0.503], t(1498)=4.65, p<0.001$. Second, the relationship between perceived norms and the likelihood of hiring a woman was also significant ($b_Norms=0.106, SE=0.008, 95\% CI [0.089, 0.123], t(1498)=12.53, p<0.001$). Consistent with partial mediation, the effect of assignment to the *quota transparent condition* compared to the *quota hidden condition* on the likelihood of hiring a woman ($b_QuotaTransparent=0.084, SE=0.028, 95\% CI [0.032, 0.136], t(1497)=2.95, p=0.003$) decreased when controlling for perceived norms ($b_QuotaTransparent=0.047, SE=0.027, 95\% CI [-0.006, 0.100], t(1496)=1.74, p=0.082$). A 10,000-sample bootstrap analysis confirmed that this reduction in effect size was significant, $b_reduction=0.037, p<0.001$, with a bias-corrected 95% CI for the size of the indirect effect that excluded zero (95% CI [0.021, 0.055]), suggesting that participants' perceptions of the normative pressure to select a woman partially account for the effect of transparent vs. hidden quotas on willingness to hire a woman. Thus, there is evidence that perceived norms around hiring a woman mediates the effect of a transparent shortlist quota compared to a hidden shortlist quota on the likelihood of hiring a woman.

Mediation by inferred organizational values. First, there was a significant effect of assignment to the *quota transparent condition* (compared to the *quota hidden condition*) on inferred organizational values norms, $b_QuotaTransparent=0.236, SE=0.100, 95\% CI [0.038,$

0.434], $t(1498)=2.36, p=0.018$. Second, the relationship between inferred organizational values and the likelihood of hiring a woman was also significant ($b_OrgValues=0.053, SE=0.007, 95\% CI [0.039, 0.066], t(1498)=7.53, p<0.001$). Consistent with partial mediation, the effect of assignment to the *quota transparent condition* compared to the *quota hidden condition* on the likelihood of hiring a woman ($b_QuotaTransparent=0.084, SE=0.028, 95\% CI [0.032, 0.136], t(1497)=2.95, p=0.003$) decreased when controlling for inferred organizational values ($b_QuotaTransparent=0.072, SE=0.028, 95\% CI [0.021, 0.122], t(1496)=2.57, p=0.010$). A 10,000-sample bootstrap analysis confirmed that this decrease in effect size was significant, $b_reduction=0.012, p=0.018$, with a bias-corrected 95% CI for the size of the indirect effect that excluded zero (95% CI [0.002, 0.023]), suggesting that inferred organizational values may also partially contribute to the effect of transparent (vs. hidden) quotas on hiring women.

No mediation by reactance. First, there was no significant effect of assignment to the *quota transparent condition* (compared to the *quota hidden condition*) on reactance, $b_QuotaTransparent=0.064, SE=0.086, 95\% CI [-0.110, 0.238], t(1498)=0.746, p=0.456$. Since there was also no relationship between reactance and the likelihood of hiring a woman ($b_Reactance=0.004, SE=0.008, 95\% CI [-0.011, 0.020], t(1498)=0.574, p=0.566$), the pattern of results is not consistent with mediation. Indeed, the 95% bias-corrected confidence interval for the indirect effect of reactance included zero, 95% CI [-0.001, 0.003].

No mediation by perceived fairness of the evaluation process. First, there was no significant effect of assignment to the *quota transparent condition* (compared to the *quota hidden condition*) on perceived fairness, $b_QuotaTransparent=-0.073, SE=0.0875, 95\% CI [-0.221, 0.075], t(1498)=-0.974, p=0.330$. There was a significant relationship between perceived fairness and the likelihood of hiring a woman ($b_Fairness=-0.019, SE=0.009, 95\% CI [-0.037, -0.001], t(1498)=-2.06, p=0.039$). These results suggest that we would not find evidence of mediation by perceived fairness; indeed, the 95% bias-corrected confidence interval for the indirect effect included zero, 95% CI [-0.001, 0.005].

Experiment 2a

Cronbach's alpha for mediator measures. We measured participants' 1) perception of the norms around selecting women (3-item scale; Cronbach's $\alpha=0.86$), 2) inferred organizational values (2-item scale; Cronbach's $\alpha=0.93$), 3) reactance (2-item scale adapted from (69); Cronbach's $\alpha=0.96$), and 4) perception of the fairness of the evaluation process (2-item scale adapted from (70); Cronbach's $\alpha=0.90$).

Robustness checks. Shortlist Decisions. We ran a Mann-Whitney U test ($U=151134, p<0.001$), OLS regression with robust standard errors ($b_ShortlistQuota=0.473, SE=0.036, 95\% CI [0.413, 0.533], t(1498)=13.40, p<0.001$) and Poisson regression ($b_ShortlistQuota=0.505, SE=0.060, 95\% CI [0.388, 0.624], z(1498)=8.40, p<0.001$) to compare the number of women included in participants' finalist sets across conditions and found similar results to our main analysis. Specifically, all robustness checks suggest more women are included in finalist teams in the *shortlist quota condition*. Our results are also robust to controlling for participant gender,

$b_ShortlistQuota=0.464$, $SE=0.035$, 95% CI [0.405, 0.524], $t(1497)=13.33$, $p<0.001$. We also find that participants who identify as men (as compared to participants who identify as women or non-binary) are less likely to select more women, $b_Men=-0.140$, $SE=0.028$, 95% CI [-0.196, -0.084], $t(1497)=-4.91$, $p<0.001$.

Hiring Decisions. We ran two-sample tests of proportions comparing the proportion of women hired in the *control condition* (20.4%) vs. the (pooled) *quota conditions* (35.0%), $\chi^2(1)=33.75$, $p<0.001$, 95% CI [-0.192, -0.100], and found similar results to our main analysis. We also compared the proportion of women hired in the *quota hidden condition* (35.4%) vs. *control condition* ($\chi^2(1)=27.96$, $p<0.001$, 95% CI [-0.205, -0.095]), *quota transparent condition* (34.6%) vs. *control condition* ($\chi^2(1)=25.28$, $p<0.001$, 95% CI [-0.197, -0.087]), and *quota hidden condition* vs. *quota transparent condition* ($\chi^2(1)=0.70$, $p=0.791$, 95% CI [-0.067, 0.051]), and found results consistent with those presented in the main text.

We also ran a logistic regression predicting the likelihood of hiring a woman as a function of assignment to the pooled *quota conditions*, $LO_QuotaPooled=0.742$, $SE=0.129$, $z=5.74$, $p<0.001$ and a logistic regression with indicators for the *quota hidden condition*, $LO_QuotaHidden=0.760$, $SE=0.145$, $z=5.24$, $p<0.001$ and *quota transparent condition*, $LO_QuotaTransparent=0.725$, $SE=0.145$, $z=4.98$, $p<0.001$. Again, the results of these robustness checks are consistent with our primary pre-registered analyses in the main text

Exploratory analyses. *Moderation by participant gender, race, and political orientation.*

Shortlist decision. First, we explored the interaction between participant gender and the presence of a shortlist quota via an exploratory OLS regression with robust standard errors to predict the number of women selected. We find that the interaction between participant gender and assignment to the *shortlist quota condition* is marginally significant ($b_ShortlistQuota \times Men=0.128$, $SE=0.070$, 95% CI [-0.009, 0.265], $t(1496)=1.83$, $p=0.068$). Next, we explored moderation by participant race using the same exploratory regression procedure. We ran an exploratory OLS regression with robust standard errors predicting the number of women selected with an indicator for assignment to the *shortlist quota condition*, a binary indicator for whether the participant was monoracial White or not, and the interaction between the two indicators. We did not find a significant interaction between participant race and assignment to the *shortlist quota condition* ($ps>0.05$). Finally, we exploited moderation by participant political orientation using the same exploratory regression procedure (a binary indicator for assignment to the *shortlist quota condition*, a predictor for political orientation (1=Extremely conservative to 7=Extremely liberal) and the interaction of the two. We did not find a significant interaction between participant political orientation and assignment to condition ($ps>0.05$).

Hiring decision. First, we explored the interaction between participant gender and assignment to the *quota hidden condition* and the interaction between participant gender and assignment to the *quota transparent condition* via an exploratory OLS regression with robust standard errors to predict the likelihood a woman was selected. Next, we explored moderation by participant race using the same exploratory regression procedure (i.e., a binary indicator for whether the participant was monoracial White or not), and the interactions between the *quota*

hidden and *quota transparent condition* indicators. We did not find a significant interaction between participant gender and assignment to either *quota* condition nor participant race and assignment to either *quota* condition ($ps > 0.05$). Finally, we explored moderation by participant political orientation using the same exploratory regression procedure. We find that the interaction between participant political orientation and assignment to the *quota condition* is significant ($b_ShortlistQuota-x-PoliticalOrientation = 0.028$, $SE = 0.013$, 95% CI [0.003, 0.053], $t(1496) = 2.20$, $p = 0.028$). This shows that the effect of the quota was greater for more politically liberal participants. Importantly, however, the predicted effect of the quota was positive for all levels of political orientation, including the most conservative participants (using coefficients from this regression model to predict the effect of the quota for each value of political orientation).

Experiment 2b

Cronbach's alpha for mediator measures. We measured participants' 1) perception of the norms around selecting women (3-item scale; Cronbach's $\alpha = 0.88$), 2) inferred organizational values (2-item scale; Cronbach's $\alpha = 0.90$), 3) reactance (2-item scale adapted from (69); Cronbach's $\alpha = 0.96$), and 4) perception of the fairness of the evaluation process (2-item scale adapted from (70); Cronbach's $\alpha = 0.88$).

Robustness checks. We ran two-sample tests of proportions comparing the proportion of women hired in the *control condition* (15.6%) vs. the (pooled) *quota conditions* (25.3%), $\chi^2(1) = 18.24$, $p < 0.001$, 95% CI [-0.139, -0.055], and found similar results to our main analysis. We also compared the proportion of women hired in the *quota hidden condition* (21.8%) vs. *control condition* ($\chi^2(1) = 6.32$, $p = 0.012$, 95% CI [-0.110, -0.014]), *quota transparent condition* (28.8%) vs. *control condition* ($\chi^2(1) = 25.22$, $p < 0.001$, 95% CI [-0.183, -0.081]), and *quota hidden condition* vs. *quota transparent condition* ($\chi^2(1) = 6.48$, $p = 0.011$, 95% CI [0.016, 0.124]), and found results consistent with those presented in the main text.

We also ran a logistic regression predicting the likelihood of hiring a woman as a function of assignment to the pooled *quota conditions*, $LO_QuotaPooled = 0.606$, $SE = 0.143$, $z = 4.23$, $p < 0.001$ and a logistic regression with indicators for the *quota hidden condition*, $LO_QuotaHidden = 0.411$, $SE = 0.164$, $z = 2.51$, $p = 0.012$ and *quota transparent condition*, $LO_QuotaTransparent = 0.783$, $SE = 0.158$, $z = 4.96$, $p < 0.001$. Again, the results of these robustness checks are consistent with our primary pre-registered analyses in the main text

Exploratory analyses. Moderation by participant gender, race, and political orientation.

First, we explored the interaction between participant gender and assignment to the *quota hidden condition* and the interaction between participant gender and assignment to the *quota transparent condition* via an exploratory OLS regression with robust standard errors to predict the likelihood a woman was selected. We find that the interaction between participant gender and assignment to the *quota transparent condition* is significant ($b_QuotaTransparent-x-Men = -0.137$, $SE = 0.053$, 95% CI [-0.241, -0.034], $t(1496) = -2.59$, $p = 0.010$) as is the interaction between

participant gender and assignment to the *quota hidden condition* ($b_QuotaHidden-x-Men=-0.134$, $SE=0.051$, 95% CI [-0.238, -0.030], $t(1496)=-2.64$, $p=0.008$)

Next, we explored moderation by participant race using the same exploratory regression procedure (i.e., a binary indicator for whether the participant was monoracial White or not), and the interactions between the *quota hidden* and *quota transparent* condition indicators. We did not find a significant interaction between participant race and assignment to either *quota condition* ($ps>0.05$). Finally, we explored moderation by participant political orientation using the same exploratory regression procedure. We did not find a significant interaction between participant political orientation and assignment to either *quota condition* ($ps>0.05$).

Experiment S1a

Robustness checks. We ran a Mann-Whitney U test ($U=151451$, $p<0.001$), OLS regression with robust standard errors ($b_ShortlistQuota=0.467$, $SE=0.035$, 95% CI [0.408, 0.526], $t(1498)=13.43$, $p<0.001$) and Poisson regression ($b_ShortlistQuota=0.499$, $SE=0.060$, 95% CI [0.382, 0.618], $z(1498)=8.30$, $p<0.001$) to compare the number of women included in participants' finalist sets across conditions and found similar results to our main analysis. Specifically, all robustness checks suggest more women are included in finalist teams in the *shortlist quota condition*. Our results are also robust to controlling for participant gender, $b_ShortlistQuota=0.462$, $SE=0.034$, 95% CI [0.404, 0.521], $t(1497)=13.41$, $p<0.001$. We also find that participants who identify as men (as compared to participants who identify as women or non-binary) are less likely to select more women, $b_Men=-0.137$, $SE=0.028$, 95% CI [-0.192, -0.082], $t(1497)=-4.89$, $p<0.001$.

Exploratory analyses. We examined whether there were condition-based differences in the likelihood of selecting all-women finalist sets and found no difference between the *control condition* (1.8%) and *shortlist quota condition* (2.1%), $\chi^2(1)=0.153$, $p=0.696$, 95% CI [-0.018, 0.012].

Moderation by participant gender and race. In order to understand the impact of participant gender on our results, we ran an exploratory OLS regression with robust standard errors predicting the number of women selected with our usual predictors (including whether the participant was male) but we added an interaction between our indicator for participants identifying as male and assignment to the *shortlist quota condition*. We found a significant interaction such that men were more affected by the shortlist quota than women and non-binary participants ($b_ShortlistQuota-x-Men=0.158$, $SE=0.069$, 95% CI [0.042, 0.274], $t(1496)=2.29$, $p=0.022$). This interaction appears to arise primarily because men included significantly fewer women in their finalist sets in our control condition than did women or non-binary participants ($b_Men=-0.242$, $SE=0.063$, 95% CI [-0.337, -0.147], $t(1496)=-3.48$, $p<0.001$). Next, we explored moderation by participant race using the same exploratory regression procedure and also did not find significant interactions between participant race (the participant being "White" or non-White) and assignment to the *shortlist quota condition* ($ps>0.05$).

Experiment S1b

Robustness checks. We first examined our analyses predicting rates of hiring a woman with an indicator for assignment to the (pooled) *quota conditions*. Our OLS regression results from the main manuscript are robust to controlling for participant gender, $b_QuotaPooled=0.108$, $SE=0.021$, 95% CI [0.064, 0.151], $t(1497)=5.15$, $p<0.001$. We also find that participants who identify as men (as compared to women, non-binary, and other gender participants) are less likely to hire a woman, $b_Men=-0.092$, $SE=0.021$, 95% CI [-0.134, -0.051], $t(1497)=-4.42$, $p<0.001$. Similarly, we replicate the results from our primary pre-registered analyses when we control for participant gender and include separate indicators for assignment to the *quota hidden condition*, $b_QuotaHidden=0.071$, $SE=0.024$, 95% CI [0.020, 0.121], $t(1496)=2.90$, $p=0.004$ and *quota transparent condition*, $b_QuotaTransparent=0.145$, $SE=0.026$, 95% CI [0.094, 0.195], $t(1496)=5.66$, $p<0.001$. Again, participants who identify as men are less likely to hire a woman, $b_Men=-0.093$, $SE=0.021$, 95% CI [-0.134, -0.051], $t(1497)=-4.44$, $p<0.001$.

We ran two-sample tests of proportions comparing the proportion of women hired in the *control condition* (14.6%) vs. the (pooled) *quota conditions* (25.5%), $\chi^2(1)=23.18$, $p<0.001$, 95% CI [-0.150, -0.068], and found similar results to our main analysis. We also compared the proportion of women hired in the *quota hidden condition* (21.8%) vs. *control condition* ($\chi^2(1)=8.71$, $p=0.003$, 95% CI [-0.120, -0.024]), *quota transparent condition* (29.2%) vs. *control condition* ($\chi^2(1)=31.16$, $p<0.001$, 95% CI [-0.196, -0.096]), and *quota hidden condition* vs. *quota transparent condition* ($\chi^2(1)=7.21$, $p=0.007$, 95% CI [-0.128, -0.020]), and found results consistent with those presented in the main text.

We also ran a logistic regression predicting the likelihood of hiring a woman as a function of assignment to the pooled *quota conditions*, $LO_QuotaPooled=0.694$, $SE=0.146$, $z=4.76$, $p<0.001$ and a logistic regression with indicators for the *quota hidden condition*, $LO_QuotaHidden=0.489$, $SE=0.167$, $z=2.93$, $p=0.003$ and *quota transparent condition*, $LO_QuotaTransparent=0.881$, $SE=0.160$, $z=5.49$, $p<0.001$. Again, the results of these robustness checks are consistent with our primary pre-registered analyses in the main text.

Exploratory analyses. *Moderation by participant gender and race.* To assess whether participant gender impacted our results, we ran an exploratory OLS regression with robust standard errors to predict whether a given participant selected a woman to join their team. Our primary predictors were an indicator for assignment to the *quota transparent condition*, an indicator for assignment to the *quota hidden condition*, and a binary indicator for participant gender (man=1, woman, non-binary, or another gender=0), and the interaction between these indicators. We did not find significant interactions between participant gender and assignment to either experimental condition ($ps>0.05$). Next, we explored moderation by participant race using the same exploratory regression procedure and also did not find significant interactions between participant race (the participant being “White” or non-White) and assignment to either experimental condition ($ps>0.05$).

In order to further unpack the mechanical impact from the signaling impact of the shortlist quota, we ran an exploratory OLS regression with robust standard errors to predict whether a given participant selected a woman to join their team including three primary predictors: an indicator for assignment to the *quota hidden condition*, an indicator for assignment to the *quota transparent condition*, and a control for the number of women finalists shown to the participant. This analysis allows us to quantify how the *quota transparent condition* impacts the number of women in the finalist set after holding constant the mechanical effects of the number of women in the choice set. We found (unsurprisingly) that the number of women finalists presented to a participant significantly increased the likelihood of hiring a woman ($b_NumWomenFinalists=0.208$, $SE=0.018$, 95% CI [0.171, 0.244], $t(1496)=11.52$, $p<0.001$). Further, since the only difference between the *control condition* and *quota hidden condition* is the difference in how many women finalists are present at the hiring stage (as mandated by the shortlist quota), controlling for the number of women in the finalist sets eliminates any statistical difference between the *quota hidden condition* and the *control condition* ($b_QuotaHidden=-0.025$, $SE=0.026$, 95% CI [-0.027, 0.077], $t(1496)=-0.944$, $p=0.345$). Most notably, even after controlling for the number of women in the finalist set, we still see a marginal increase in the likelihood participants hire a woman in the *quota transparent condition* compared to the *control condition* ($b_QuotaTransparent=0.049$, $SE=0.028$, 95% CI [-0.003, 0.100], $t(1496)=1.73$, $p=0.085$), providing further suggestive evidence that shortlist quotas have signaling as well as mechanical effects. Of note though, our experimental design and pre-registered analysis comparing the outcomes of the *quota hidden* and *quota transparent* conditions are a cleaner and stronger test of the signaling effects of the shortlist quota.

We also examined whether there were condition-based differences in performance. We ran an OLS regression with robust standard errors to predict team scores as a function of assignment to the pooled *quota conditions*, but did not find a significant difference in performance, $b_QuotaPooled=0.152$, $SE=0.103$, 95% CI [-0.051, 0.355], $t(1498)=1.47$, $p=0.141$. Similarly, we also did not find a significant difference in team performance when we included separate indicators for assignment to the *quota hidden condition*, $b_QuotaHidden=0.082$, $SE=0.121$, 95% CI [-0.153, 0.317], $t(1497)=0.68$, $p=0.497$ and *quota transparent condition*, $b_QuotaTransparent=0.222$, $SE=0.118$, 95% CI [-0.013, 0.457], $t(1497)=1.87$, $p=0.061$.

Finally, we examined whether win probabilities differed across *control condition*, *quota hidden condition*, and *quota transparent condition* teams. We first ran Mann-Whitney U tests to assess whether teams had equal likelihood of winning (i.e., whether for a randomly selected quota team Q and control team C the likelihood of Q being greater than C is equal to the likelihood of C being greater than Q). We also calculated the win likelihood by using the following equation ($U/(n1*n2)$; nk is the number of observations in group k).

We found no significant differences between the *control condition* vs. pooled *quota conditions* (win probability=47.7%), $U=238688$, $p=0.146$. Similarly, we found no significant differences between the *control* vs. *quota hidden conditions* (win probability=48.3%), $U=120834$, $p=0.354$, no significant difference between the *control* vs. *quota transparent*

conditions (win probability=47.1%), $U=117854$, $p=0.112$, and no significant difference between the *quota hidden* vs. *quota transparent conditions* (win probability=48.9%), $U=122356$, $p=0.556$.

Experiment S2a

Robustness checks. We ran a Mann-Whitney U test ($U=222561$, $p<0.001$), OLS regression with robust standard errors ($b_ShortlistQuota=0.165$, $SE=0.038$, 95% CI [0.098, 0.232], $t(1498)=4.37$, $p<0.001$) and Poisson regression ($b_ShortlistQuota=0.129$, $SE=0.049$, 95% CI [0.033, 0.225], $z(1498)=2.63$, $p=0.009$) to compare the number of women included in participants' finalist sets across conditions and found similar results to our main analysis. Specifically, all robustness checks suggest more women are included in finalist teams in the *shortlist quota condition*. Our results are also robust to controlling for participant gender, $b_ShortlistQuota=0.165$, $SE=0.032$, 95% CI [0.098, 0.232], $t(1497)=4.37$, $p<0.001$.

Exploratory analyses. *Moderation by participant gender, race, and political orientation.* In order to understand the impact of participant gender on our results, we ran an exploratory OLS regression with robust standard errors predicting the number of women selected with our usual predictors (including whether the participant was male) but we added an interaction between our indicator for participants identifying as male and assignment to the *shortlist quota condition*. We did not find a significant interaction between participant gender and assignment to *shortlist quota condition* ($ps>0.05$). In order to understand the impact of participant race on our results, we ran an exploratory OLS regression with robust standard errors predicting the number of women selected with an indicator for assignment to the *shortlist quota condition*, a binary indicator for whether the participant was monoracial White or not, and the interaction between the two indicators. We did not find a significant interaction between participant race and assignment to the *shortlist quota condition* ($ps>0.05$). In order to understand the impact of participant political orientation on our results, we ran an exploratory OLS regression with robust standard errors predicting the number of women selected with an indicator for assignment to the *shortlist quota condition*, the political orientation scale (1=Extremely conservative to 7=Extremely liberal), and the interaction between the two. We did not find a significant interaction between participant political orientation and assignment to the *shortlist quota condition* ($ps>0.05$).

Moderation by female-dominated vs. male-dominated environments. We tested whether the effect of the shortlist quota was moderated by the relative qualifications of male and female candidates available for selection. We exploited the fact that the candidate pools of seven men and three women were randomly drawn from a set of fifty candidates for each participant, providing random variation in the relative qualifications (i.e., practice round scores) of women vs. men in candidate pools. Specifically, we calculated the expected average team score when randomly selecting a man vs. a woman as the final hire from each candidate pool. When selecting women would, on average, improve team scores relative to selecting men, we defined the candidate pool as "female-dominated", and vice versa.

First, we assessed the effect of shortlist quotas in each type of candidate pool separately. In male-dominated candidate pools, we found that participants included significantly more women in the *shortlist quota condition* ($M=1.15$, $SD=0.42$) than in the *control condition* ($M=0.76$, $SD=0.64$); $t(386)=7.292$, $p<0.001$). By contrast, in female-dominated pools, participants in the *shortlist quota condition* included only directionally more women in the shortlist ($M=1.44$, $SD=0.57$) than in the *control condition*, where the number of women shortlisted was already high ($M=1.38$, $SD=0.72$); $t(1100)=1.57$, $p=0.115$). Next, we test for moderation with an OLS regression predicting the number of women finalists selected with an indicator for assignment to the quota condition, an indicator for whether the decision-maker was assigned a female-dominated candidate pool, and the interaction of the two. We found that the impact of the quota on the number of women shortlisted was significantly moderated by whether the environment was female- vs. male-dominated, $b_FemaleDominated \times Quota = -0.334$, $SE=0.075$, 95% CI $[-0.478, -0.190]$, $t(1496)=-4.469$, $p<0.001$.

Evidence of sabotaging the quota. To assess whether the shortlist quota prompted decision-makers to sabotage the quota's ultimate goal, by deliberately shortlisting women that were unlikely to be selected in the final hiring decision, we measured the extent to which decision-makers selected only the lowest qualified woman in the candidate pool (according to their practice round scores), and whether this differed between the *quota condition* and *control condition*. Overall, we found limited selection of only the least qualified woman, however, we found that significantly more participants included only the least qualified woman in their shortlist in the *shortlist quota condition* ($M=2.8\%$) than in the *control condition* ($M=1.2\%$); $t(1498)=1.964$, $p=0.0497$). This pattern could be driven by (i) deliberate effort to undermine the shortlist quota policy (by choosing women unlikely to be hired simply to fulfil the quota), or (ii) limited attention: those who would not have picked a female candidate but for the quota might pay less attention in determining which female candidates are best. To further unpack this pattern, we test for whether the quota's effect on selecting the lower quality female candidate was mediated by the negative signals we measure (reactance or perceived fairness) independently using a 10,000-sample bootstrapped mediation model. We find evidence consistent with mediation by reactance – the bias-corrected 95% CI for the size of the indirect effect of reactance excluded zero (95% CI $[0.0002, 0.0005]$) – but not of perceived fairness (Indirect Effect 95% CI $[-0.0013, 0.0016]$). There is thus some evidence that the shortlist quota induced some decision-makers experiencing reactance to select the lowest-quality female candidate. This appears relatively limited, applying to $\sim 1.6\%$ of participants, and could be attributed to either deliberate sabotage or applying less attention to selecting female candidates.

The effect of the quota on shortlist quality. We find that the quota had no effect on the quality of finalists selected: there was no difference in the average predicted team score (using practice round scores to predict team scores) for finalists selected under the *shortlist quota condition* ($M=25.02$, $SD=1.30$) compared to finalists selected in the *control condition* ($M=25.09$, $SD=1.23$); $t(1498)=-1.079$, $p=0.281$).

Experiment S2b

Robustness checks. We ran two-sample tests of proportions comparing the proportion of women hired in the *control condition* (60.8%) vs. the (pooled) *quota conditions* (66.7%), $\chi^2(1)=5.08, p=0.024$, 95% CI [-0.110, -0.007], and found similar results to our main analysis. We also compared the proportion of women hired in the *quota hidden condition* (67.6%) vs. *control condition* ($\chi^2(1)=5.03, p=0.025$, 95% CI [-0.127, -0.009]), *quota transparent condition* (65.8%) vs. *control condition* ($\chi^2(1)=2.69, p=0.101$, 95% CI [-0.110, 0.010]), and *quota hidden condition* vs. *quota transparent condition* ($\chi^2(1)=0.365, p=0.546$, 95% CI [-0.040, 0.076]), and found results consistent with those presented in the main text.

We also ran a logistic regression predicting the likelihood of hiring a woman as a function of assignment to the pooled *quota conditions*, $LO_QuotaPooled=0.256, SE=0.113, z=1.25, p=0.024$ and a logistic regression with indicators for the *quota hidden condition*, $LO_QuotaHidden=0.297, SE=0.132, z=2.24, p=0.025$ and *quota transparent condition*, $LO_QuotaTransparent=0.215, SE=0.131, z=1.64, p=0.101$. Again, the results of these robustness checks are consistent with our primary pre-registered analyses in the main text.

Exploratory analyses. *Moderation by participant gender, race, and political orientation.* In order to understand the impact of participant gender on our results, we ran an exploratory OLS regression with robust standard errors predicting whether a woman was selected with an indicator for assignment to the *quota transparent condition*, *quota hidden condition*, an indicator for whether the participant identified as a man, and the two-way interactions between conditions and gender. We did not find significant interactions ($b_QuotaTransparent-x-Men=-0.010, SE=0.062, 95\% CI [-0.130, 0.109], t(1496)=-0.171, p=0.865$; $b_QuotaHidden-x-Men=-0.029, SE=0.061, 95\% CI [-0.148, 0.090], t(1496)=-0.474, p=0.636$). When we ran a second exploratory OLS regression with robust standard errors without the interactions described above, we found that men were significantly less likely to select a woman ($b_Men=-0.071, SE=0.025, 95\% CI [-0.120, -0.023], t(1496)=-2.86, p=0.004$).

To assess whether participant race impacted our results, we ran an exploratory OLS regression with robust standard errors to predict whether a given participant selected a woman to join their team. Our primary predictors were an indicator for assignment to the *quota transparent condition*, an indicator for assignment to the *quota hidden condition*, and a binary indicator for participant race (monoracial White=1, non-White=0), and the interaction between these indicators. We did not find significant interactions between participant race and assignment to either experimental condition ($ps>0.05$).

In order to understand the impact of participant political orientation on our results, we ran an exploratory OLS regression with robust standard errors for whether a woman was selected with an indicator for assignment to the *quota transparent condition*, an indicator for assignment to the *quota hidden condition*, the political orientation scale (1=Extremely conservative to 7=Extremely liberal), and the interactions between the political orientation scale and each *quota condition*. There was significant moderation by political orientation such that more liberal participants in the *quota transparent condition* were more likely to select a woman ($b_QuotaTransparent-x-PolOrient=0.048, SE=0.017, 95\% CI [0.016, 0.080], t(1496)=2.89, p=0.004$). We do not find a significant difference in moderation between the *quota hidden condition* and *quota transparent condition*.

Moderation by female-dominated vs. male-dominated environments. As in Experiment S2a, we tested for moderation of the effects of shortlist quotas by the relative qualifications of men and women in the original candidate pools used to select the shortlists. As in Experiment S2a, we divided candidate pools into those that were “male-dominated” (where men were more qualified than women in the original candidate pool on average) vs. “female-dominated” (where women were more qualified).

First, we assess the effect of the shortlist quota on whether a woman was hired in each of male-dominated and female-dominated environments, separately. We ran an exploratory OLS regression with robust standard errors predicting whether a woman was hired with an indicator for assignment to the *pooled quota conditions*, exclusively with participants assigned male-dominated candidate pools. We found that the the pooled quota had a significant effect on the likelihood a woman was chosen in these male-dominated environments ($b_PooledQuota=0.125$, $SE=0.049$, 95% CI [0.026, 0.224], $t(386)=2.527$, $p=0.012$). We then ran the same model exclusively with participants assigned female-dominated candidate pools, and found no effect of the pooled quota: ($b_PooledQuota=0.018$, $SE=0.028$, 95% CI [-0.036, 0.072], $t(1110)=0.6361$, $p=0.525$). We then ran a model predicting the likelihood of selecting a woman on an indicator for assignment to the pooled quota conditions, an indicator for being assigned a female-dominated candidate pool, and the interaction of the two. We found directional (but non-significant) evidence of moderation of the effect of shortlist quotas on hiring women based on whether the original candidate pool was female-dominated, $b_FemaleDominated-x-PooledQuota=-0.107$, $SE=0.055$, 95% CI [-0.215, 0.001], $t(1496)=-1.94$, $p=0.053$.

We then ran a separate set of models assessing the effect of the quota hidden and quota transparent conditions separately on the likelihood of selecting a woman in each of male-dominated and female-dominated environments. We found that in male-dominated environments, the *quota hidden condition* increased the likelihood of selecting a woman relative to the control condition ($b_QuotaHidden=0.152$, $SE=0.058$, 95% CI [0.038, 0.266], $t(385)=2.621$, $p=0.009$, but that the *quota transparent condition* did not ($b_QuotaTransparent=0.094$, $SE=0.059$, 95% CI [-0.023, 0.212], $t(385)=1.601$, $p=0.110$). We did not observe a significant difference between the effect of the *quota transparent* vs. *quota hidden* conditions (difference = -0.058, $t(385)=-0.923$, $p=0.356$), indicating no evidence of communication effects of the quota in these environments. In female-dominated environments, we found that neither the *quota hidden* nor *quota transparent* conditions affected the likelihood of hiring female workers ($p>0.418$), nor was there any observable difference between the quota hidden and quota transparent conditions ($p=0.609$). When we ran an OLS regression predicting the likelihood of hiring a woman on indicators for assignment to either the quota hidden condition or the quota transparent condition, assignment of a female-dominated candidate pool, and interactions between the assignment to each quota condition separately and a female-dominated pool, we did not find evidence of significant interactions of each quota condition with the type of environment in which hiring decisions were made. However, this set of interactions suffers from lower statistical power and we find non-significant directional interaction between

the quota hidden condition and female-dominated environments $b_FemaleDominated-x-QuotaHidden=-0.126$, $SE=0.066$, 95% CI $[-0.251, 0.001]$, $t(1494)=1.90$, $p=0.058$, suggesting possibly that the pure implementation effects of the quota on the number of women hired are greater when women are disadvantaged at baseline.

Robustness Simulations Across Experiments

To assess whether random selection of candidates could explain our results in either the Shortlist Stage or Hiring Stage, we ran simulations to determine what our data would look like if study participants were choosing randomly, and we compared these simulated data to our actual data.

For the Shortlist Stage, we ran 30,000 simulations ($n_{ControlCondition}=10,000$, $n_{QuotaCondition}=20,000$) of random selections of finalist sets, and then we compared this simulated data to the pooled results of Experiments S1a and 1a. As shown in Supplementary Fig. S3, the distributions of the simulated finalist sets (Panel B) and real experimental data (Panel A) differ significantly in both the control condition and the shortlist quota condition, suggesting that participants are not randomly selecting finalists in either experiment condition (*control condition*: $\chi^2(3)=76.40$, $p<0.001$; *shortlist quota condition*: $\chi^2(2)=460.21$, $p<0.001$).

For the Hiring Stage, we ran simulations of random selection based on the finalist sets generated across Experiments S1a and 1a. We simulated 10,000 random hires for each of the 3,000 finalist sets from Experiments S1a and 1a. We then compared this simulated data to the data from real selection decisions pooling across Experiments S1b and 1b (see Supplementary Fig. S4). When we examined the simulation results, we saw that an average of 24.2% women ($SE=0.01\%$) would be selected in the *control condition* with random choosing (vs. 14.1% observed in pooled Experiments 1b and 2b, $\chi^2(1)=51.27$, $p<0.001$), 40.0% women ($SE=0.01\%$) would be selected in the *quota hidden condition* with random choosing (vs. 23.0% observed in pooled Experiments S1b and 1b, $\chi^2(1)=109.99$, $p<0.001$), and 40.0% women ($SE=0.01\%$) would be selected in the *quota transparent condition* with random choosing (vs. 30.9% observed in pooled Experiments 1b and 2b, $\chi^2(1)=31.05$, $p<0.001$). These differences suggest that decision-makers in Experiments S1b and 1b were not selecting hires randomly, and if they were, that we also would not have observed differences between the *quota hidden* and *quota transparent* conditions (which we did).

Materials

Candidate Pool

[Name]

Please tell us how we should refer to you. You can use your initials (or a pseudonym if you would prefer):

[Instructions]

Hi linda,

Today you will be participating in three different games. We will explain each of the games in more detail before you play them. At the end of each game you will learn how many questions you answered correctly. For each correct answer, you will earn a bonus of \$0.05. This bonus will be added to your base pay of: \$3.00.

The first game is a **Math Game**, the second game is an **Angles Game**, and the third game is a **Trivia Game**. Each of these games will have two rounds.

Please click the arrow to continue to the first game.

[Math Game Instructions]

Welcome to the Math Game! This game will take place in two rounds.

For each question, you will be presented with two objects, like the ones below. Your goal is to determine if these two objects are **the same or different**.

For example, the **two objects below are the same**. If you rotate the object on the left, it is identical to the one on the right.

However, the **two objects below are different**. There is no way to rotate the object on the left so that it is identical to the one on the right.

For each correctly answered question, you will earn \$0.05. You will have 7 seconds to answer each question before the page automatically advances. Please answer questions honestly without outside help.

Please click the arrow when you are ready to start.

[Example Math Game question]

07

Are these objects the same or different?

Same

Different

[Instructions between Math Game rounds]

Thank you for completing the first round of the Math Game.

Please click the arrow to continue to the second (and final) round of the Math Game.

Remember that you will earn a bonus of \$0.05 for each correctly answered question.

[Feedback after both Math Game rounds]

linda, here are your results on the Math Game!

You scored a total of 0 points.

Please click the arrow to continue to the next game.

[Instructions for Angles Game]

Welcome to the Angles Game! This game will take place in two rounds.

You will be shown a line that looks like this:

Underneath it, you'll see a set of 15 lines with corresponding numbered labels:

Your task is to identify which line in the set matches the angle of the single line.

For each correctly answered question, you will earn \$0.05. You will have 7 seconds to answer each question before the page automatically advances. Please answer questions honestly without outside help.

Please click the arrow when you are ready to start.

[Example Angles Game question]

07

The line above corresponds to which number?

[Instructions between Angles Game rounds]

Thank you for completing the first round of the Angles Game.

Please click the arrow to continue to the second (and final) round of the Angles Game.

Remember that you will earn a bonus of \$0.05 for each correctly answered question.

[Feedback after both Math Game rounds]

linda, here are your results on the Angles Game!

You scored a total of 3 points!

Please click the arrow to continue to the next game.

[Instructions for Trivia Game]

Welcome to the Trivia Game! This game will take place in two rounds.

For each correctly answered question, you will earn \$0.05. You will have 7 seconds to answer each question before the page automatically advances. Please answer questions honestly without outside help.

Please click the arrow when you are ready to start.

[Example Trivia Game question]

Which of the following is NOT the name of one of Angelina Jolie's children?

☐ Maddox

☐ Zahara

☐ Knox

☐ Pax

☐ Marley

[Instructions between Trivia Game rounds]

Thank you for completing the first round of the Trivia Game.

Please click the arrow to continue to the second (and final) round of the Trivia Game.

Remember that you will earn a bonus of \$0.05 for each correctly answered question.

[Feedback after both Trivia Game rounds]

linda, here are your results on the Trivia Game!

You scored a total of 2 points!

Please click the arrow to complete a few more questions.

[Demographics]

Please complete the following demographic information.

How old are you?

 years old

What is your gender?

- ☐ Man
- ☐ Woman
- ☐ Non-binary
- ☐ Another gender not listed here

What is your racial or ethnic background and heritage? Please check all that apply.

- ☐ Black/African American
- ☐ White
- ☐ East Asian
- ☐ South Asian
- ☐ Southeast Asian
- ☐ Hispanic/Latinx
- ☐ Native American/Native Alaskan
- ☐ Native Hawaiian/Pacific Islander
- ☐ Not listed (please specify)

[Demographics continued]

What is your highest education level?

- ☐ Some high school
- ☐ High school graduate or equivalent
- ☐ Some college credit
- ☐ Bachelor's degree
- ☐ Master's degree
- ☐ Professional degree
- ☐ Doctorate degree

What is your occupation?

What is your home state?

What is your previous experience with games like these?

- ☐ Not experienced at all
- ☐ Slightly experienced
- ☐ Moderately experienced
- ☐ Very experienced
- ☐ Extremely experienced

Experiment 1a

[Instructions- As participants advanced in the survey, we faded previous instructions paragraphs to draw attention to the new information. The instructions you see below unfolded over 5 screens.]

Today you will select finalists from a set of candidates to join a team that already includes two players. You will be paid a bonus based on your team's performance in a round of games that will take place after your team is selected. You will not be part of the team nor will you participate in the games.

The candidates to join your team have completed a practice round of three different games where they answered a total of 30 multiple choice questions and were paid for each question they answered correctly.

In the first of three games candidates played (which we called "the Math Game"), candidates were presented with two objects, like the ones below. They had 7 seconds to decide whether these objects were the same or different.

In the second of three games candidates played (which we called "the Angles Game"), candidates were shown a line, like the one below, and given 7 seconds to identify which numbered line in the set matches the angle of the single line.

In the third of three games candidates played (which we called "the Trivia Game"), candidates were given 7 seconds to answer multiple choice trivia questions, like the one below.

Which mixing method incorporates ingredients with a spatula?

- a. Beating
- b. Folding
- c. Sifting
- d. Whipping
- e. Creaming

[Instructions 2]

You can use the information provided about each candidate to **select three finalists for your team** to play the same three types of games for you “for real” and for payment. Another Prolific worker will choose **one** of your finalists to join your team, which means your final team will have three players.

Your bonus payment will depend on your final team's performance during a new round of these same three types of games. In this new round, each member of your team will answer 30 multiple choice questions. Your team will be randomly matched to compete against another team. Your overall team score will be calculated by identifying the team member with the highest score on a game and adding these highest scores across the three different games. The team that has the highest overall team score will win the matchup. If your team wins, you will earn a \$1.00 bonus. If your team ties or loses, you will not receive a bonus.

[Comprehension checks]

Today you will select finalists from a set of candidates to join a team that already includes two players. You will be paid a bonus based on your team's performance in a round of games that will take place after your team is selected. You will not be part of the team nor will you participate in the games.

You can use the information provided about each candidate to **select three finalists for your team** to play the same three types of games for you "for real" and for payment. Another Prolific worker will choose **one** of your finalists to join your team, which means your final team will have three players.

Your overall team score will be calculated by identifying the team member with the highest score on a game and adding these highest scores across the three different games. The team that has the highest overall team score will win the matchup. If your team wins, you will earn a \$1.00 bonus. If your team ties or loses, you will not receive a bonus.

How do you earn a bonus payment?

- ☐ My team must answer more questions correctly than the competing team
- ☐ My team's overall score must be higher than the competing team
- ☐ At least one member of my team must answer the majority of questions correctly

Today you will select finalists from a set of candidates to join a team that already includes two players. You will be paid a bonus based on your team's performance in a round of games that will take place after your team is selected. You will not be part of the team nor will you participate in the games.

You can use the information provided about each candidate to **select three finalists for your team** to play the same three types of games for you "for real" and for payment. Another Prolific worker will choose **one** of your finalists to join your team, which means your final team will have three players.

Your bonus payment will depend on your final team's performance during a new round of these same three types of games. Your overall team score will be calculated by identifying the team member with the highest score on a game and adding these highest scores across the three different games. The team that has the highest overall team score will win the matchup. If your team wins, you will earn a \$1.00 bonus. If your team ties or loses, you will not receive a bonus.

Imagine the following:

Math Game

- Highest scorer of your team: 5/10
- Highest scorer of competing team: 4/10

Angles Game

- Highest scorer of your team: 7/10
- Highest scorer of competing team: 6/10

Trivia Game

- Highest scorer of your team: 8/10
- Highest scorer of competing team: 9/10

What is your overall team score?

Today you will select finalists from a set of candidates to join a team that already includes two players. You will be paid a bonus based on your team's performance in a round of games that will take place after your team is selected. You will not be part of the team nor will you participate in the games.

Your bonus payment will depend on your final team's performance during a new round of these same three types of games. In this new round, each member of your team will answer 30 multiple choice questions. Your team will be randomly matched to compete against another team. Your overall team score will be calculated by identifying the team member with the highest score on a game and adding these highest scores across the three different games. The team that has the highest overall team score will win the matchup. If your team wins, you will earn a \$1.00 bonus. If your team ties or loses, you will not receive a bonus.

Imagine the following:

Math Game

- Highest scorer of your team: 5/10
- Highest scorer of competing team: 4/10

Angles Game

- Highest scorer of your team: 7/10
- Highest scorer of competing team: 6/10

Trivia Game

- Highest scorer of your team: 8/10
- Highest scorer of competing team: 9/10

Will you receive a bonus?

☐ No

☐ Yes

[Existing team]

Before you pick finalists to round out your team, we want to introduce you to your team's two existing members. Recall that each team will have three players and you will be choosing finalists to fill the only remaining spot on your team of three.

In a moment, we will present the profiles of 10 candidates. We will ask you to select 3 finalists from this pool for your team.

Your team

Pseudonym: "Ollie"

Gender: Man

Home state: Connecticut

Previous experience: Not experienced at all

Pseudonym: "RC"

Gender: Man

Home state: Ohio

Previous experience: Slightly experienced

[Candidate pool information]

Here is some information about the average performance of different players in the practice round to help inform your selection decisions:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30
- Average score of men in the practice round: 20.0/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30

[Comprehension checks]

Here is some information about the average performance of different players in the practice round to help inform your selection decisions:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30
- Average score of men in the practice round: 20.0/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30

What was the overall average score in the practice round?

Here is some information about the average performance of different players in the practice round to help inform your selection decisions:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30
- Average score of men in the practice round: 20.0/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30

For which groups do you have the average practice round score (check all that apply)?

☐ Men and women

☐ Players from PA and CA

☐ "Not experienced at all" and "Moderately experienced"

[Finalist selection – Control Condition]

Here are the profiles of 10 candidates for you to review. Please take some time to carefully evaluate each of their profiles.

Once you have evaluated each player, please select the 3 players you'd like to designate as finalists for your team.

Candidate pool information:

- Average score in the practice round overall: 19.0/30

Thank you for selecting your finalists! We will pass this finalist list onto another Prolific worker who will choose the last member of your team. We will pay you a bonus based on your team's performance. This process should take no longer than 10 business days.

[Perceptions of social norms]

Please rate the extent to which you agree or disagree with each of the following statements:

If the list of candidates contains women, most Prolific workers should select at least one woman finalist.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

If the list of candidates contains women, most Prolific workers will select at least one woman finalist.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

Most Prolific workers completing this task think people should include at least one woman in the finalist set.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

[Inferred organizational values]

Please rate the extent to which you agree or disagree with each of the following statements:

When making my candidate selection decisions, I considered whether the organization that developed this hiring task would value including a woman on the final team of hires.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

When making my candidate selection decisions, I considered how my choices would align with the values of the organization that developed this hiring task.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

[Perceptions of fairness of the process]

Please rate the extent to which you agree or disagree with each of the following statements:

The procedure used to evaluate and select the finalists was objective.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

The procedure used to evaluate and select the finalists was fair.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

[Reactance]

Please rate the extent to which you agree or disagree with each of the following statements:

When making candidate selection decisions, I became frustrated when I was unable to make free and independent decisions.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

When making candidate selection decisions, I felt angry that my freedom of choice was being restricted.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

Mediators:

Perceived social norms

1. Most Prolific workers completing this task think people should include at least one woman in the finalist set.
2. If the list of candidates contains women, most Prolific workers will select at least one woman finalist.
3. If the list of candidates contains women, most Prolific workers should select at least one woman finalist.

Inferred organizational values

1. When making my decision, I considered how my choices would align with the values of the organization that developed this hiring task.
2. When making my decision, I considered whether the organization that developed this hiring task would value including a woman on the final team of hires.

Reactance

1. When making candidate selection decisions, I felt angry that my freedom of choice was being restricted.
2. When making candidate selection decisions, I became frustrated when I was unable to make free and independent decisions.

Perceptions of fairness of the process

1. The procedure used to evaluate and select the finalists was objective.
2. The procedure used to evaluate and select the finalists was fair.

[Demographics]

Please complete the following demographic information.

How old are you?

 years old

What is your gender?

☐ Man

☐ Woman

☐ Non-binary

☐ Another gender not listed here

What is your racial or ethnic background and heritage? Please check all that apply.

☐ Black/African American

☐ White

☐ East Asian

☐ South Asian

☐ Southeast Asian

☐ Hispanic/Latinx

☐ Native American/Native Alaskan

☐ Native Hawaiian/Pacific Islander

☐ Not listed (please specify)

Experiment 1b

[Instructions- As participants advanced in the survey, we faded previous instructions paragraphs to draw attention to the new information. The instructions you see below unfolded over 5 screens.]

Today you will select a final member to join a team that already includes two players. You will be paid based on your team's performance in a new round of games that will take place after your team is selected. You will not be part of the team or nor will you participate in the games.

The candidates to join your team have completed a practice round of three different games where they answered a total of 30 multiple choice questions and were paid for each question they answered correctly.

In the first of three games candidates played (which we called "the Math Game"), candidates were presented with two objects, like the ones below. They had 7 seconds to decide whether these objects were the same or different.

In the second of three games candidates played (which we called "the Angles Game"), candidates were shown a line, like the one below, and given 7 seconds to identify which numbered line in the set matched the angle of the single line.

In the third of three games candidates played (which we called "the Trivia Game"), candidates were given 7 seconds to answer multiple choice trivia questions, like the one below.

Which mixing method incorporates ingredients with a spatula?

- a. Beating
- b. Folding
- c. Sifting
- d. Whipping
- e. Creaming

[Instructions 2]

You can use the information provided about each candidate to **select the final member of your team**. Your team will play the same three types of games for you “for real” and for payment. The finalists you will see were selected from a larger pool of 10 candidates by a previous Prolific worker.

Your bonus payment and the bonus payment of the Prolific worker who chose this set of three finalists for you will depend on your team’s performance during a **new round** of these same three types of games. In this new round, each member of your team will answer 30 multiple choice questions. Your team will be randomly matched to compete against another team. Your overall team score will be calculated by identifying the team member with the highest score on a game and adding these highest scores across the three different games. The team that has the highest overall team score will win the matchup. If your team wins, you will earn a \$1.00 bonus. If your team ties or loses, you will not receive a bonus.

[Comprehension checks]

Will you receive a bonus?

☐ No

☐ Yes

[Existing team]

Before you pick the final player to round out your team, we want to introduce you to your team's two existing members. Recall that each team will have three players and you will be choosing one player to fill the only remaining spot on your team of three.

Remember that your team's performance in a new round of games will determine whether you receive a bonus and not the practice scores you see below.

In a moment, we will present the profiles of 3 finalists to complete your team. We will ask you to select 1 player from this set.

Your team

Pseudonym: "D"

Gender: Man

Home state: California

Previous experience: Slightly experienced

Pseudonym: "EmperorHJ"

Gender: Man

Home state: Oregon

Previous experience: Slightly experienced

[Candidate pool information]

Here is some information about the average performance of different players in the practice round to help inform your selection decisions:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30
- Average score of men in the practice round: 20.0/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30

[Comprehension checks]

Here are the profiles of 10 candidates for you to review. Please take some time to carefully evaluate each of their profiles.

Once you have evaluated each player, please select the 3 players you'd like to designate as finalists for your team.

At least 1 of the 3 finalists you select must be a woman.

Candidate pool information:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30
- Average score of men in the practice round: 20.0/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30

Here is some information about the average performance of different players in the practice round to help inform your selection decisions:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30

[Message]

Thank you for selecting your final team member! Your team will now be able to compete and we will pay you a bonus based on their performance. This process should take no longer than 20 business days.

[Perceived competence of final hire]

Below is the profile of the candidate you selected as the final team member.

Pseudonym: "KE"

Gender: Woman

Home state: Ohio

Previous experience: Moderately experienced

How many points (out of 10) do you think this candidate will earn on each of the games? After your candidate has played these games, we will compare your prediction to their actual score. You will earn \$0.05 for each accurate prediction you make, for a total of up to \$0.15 across the three games.

Math Game

Angles Game

[illegible]

[Perceptions of fairness of the process]

Please rate the extent to which you agree or disagree with each of the following statements:

The procedure used to evaluate and select the final team player was objective.

The procedure used to evaluate and select the final team player was fair.

Strongly disagree Disagree Somewhat disagree Neither agree or disagree Somewhat agree Agree Strongly agree

[Reactance]

Please rate the extent to which you agree or disagree with each of the following statements:

When making my selection decision, I felt angry that my freedom of choice was being restricted.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

When making my selection decision, I became frustrated when I was unable to make free and independent decisions.

Strongly disagree	Disagree	Somewhat disagree	Neither agree or disagree	Somewhat agree	Agree	Strongly agree
☐	☐	☐	☐	☐	☐	☐

Mediators:**Perceived social norms**

1. Most Prolific workers completing this task think people should have selected a woman as the final team member.
2. If a finalist set contains a woman, most Prolific workers will select her as the final team member.
3. If a finalist set contains a woman, most Prolific workers should select her as the final team member.

Inferred organizational values

1. When making my decision, I considered how my choices would align with the values of the organization that developed this hiring task.
2. When making my decision, I considered whether the organization that developed this hiring task would value including a woman on the final team of hires.

Reactance

1. When making my selection decision, I felt angry that my freedom of choice was being restricted.
2. When making my selection decision, I became frustrated when I was unable to make free and independent decisions.

Perceptions of fairness of the process

1. The procedure used to evaluate and select the final team player was objective.
2. The procedure used to evaluate and select the final team player was fair.

[Demographics]

Please complete the following demographic information.

How old are you?

 years old

What is your gender?

☐ Man

☐ Woman

☐ Non-binary

☐ Another gender not listed here

What is your racial or ethnic background and heritage? Please check all that apply.

☐ Black/African American

☐ White

☐ East Asian

☐ South Asian

☐ Southeast Asian

☐ Hispanic/Latinx

☐ Native American/Native Alaskan

☐ Native Hawaiian/Pacific Islander

☐ Not listed (please specify)

Experiment 2a

[Instructions- As participants advanced in the survey, we faded previous instructions paragraphs to draw attention to the new information. The instructions you see below unfolded over 5 screens.]

Today you will select finalists from a set of candidates to join a team that already includes two players. You will be paid a bonus based on your team's performance in a round of games that will take place after your team is selected. You will not be part of the team nor will you participate in the games.

The candidates to join your team have completed a practice round of three different games where they answered a total of 30 multiple choice questions and were paid for each question they answered correctly.

In the first of three games candidates played (which we called "the Math Game"), candidates were presented with two objects, like the ones below. They had 7 seconds to decide whether these objects were the same or different.

In the second of three games candidates played (which we called "the Angles Game"), candidates were shown a line, like the one below, and given 7 seconds to identify which numbered line in the set matches the angle of the single line.

In the third of three games candidates played (which we called "the Trivia Game"), candidates were given 7 seconds to answer multiple choice trivia questions, like the one below.

Which mixing method incorporates ingredients with a spatula?

- a. Beating
- b. Folding
- c. Sifting
- d. Whipping
- e. Creaming

[Instruction 2]

You can use the information provided about each candidate to **select three finalists for your team** to play the same three types of games for you “for real” and for payment. After selecting three finalists, you will choose **one** of your finalists to join your team, which means your final team will have three players.

Your bonus payment will depend on your final team's performance during a new round of these same three types of games. In this new round, each member of your team will answer 30 multiple choice questions. Your team will be randomly matched to compete against another team. Your overall team score will be calculated by identifying the team member with the highest score on a game and adding these highest scores across the three different games. The team that has the highest overall team score will win the matchup. If your team wins, you will earn a \$1.00 bonus. If your team ties or loses, you will not receive a bonus.

[Comprehension checks]

Today you will select finalists from a set of candidates to join a team that already includes two players. You will be paid a bonus based on your team's performance in a round of games that will take place after your team is selected. You will not be part of the team nor will you participate in the games.

You can use the information provided about each candidate to **select three finalists for your team** to play the same three types of games for you "for real" and for payment. After selecting three finalists, you will choose **one** of your finalists to join your team, which means your final team will have three players.

Imagine the following:

Math Game

- Highest scorer of your team: 5/10
- Highest scorer of competing team: 4/10

Angles Game

- Highest scorer of your team: 7/10
- Highest scorer of competing team: 6/10

Trivia Game

- Highest scorer of your team: 8/10
- Highest scorer of competing team: 9/10

Will you receive a bonus?

☐ Yes

☐ No

[Existing team]

Before you pick finalists to round out your team, we want to introduce you to your team's two existing members. Recall that each team will have three players and you will be choosing finalists to fill the only remaining spot on your team of three.

In a moment, we will present the profiles of 10 candidates. We will ask you to select 3 finalists from this pool for your team.

Your team

Pseudonym: "SJP"

Gender: Man

Home state: Minnesota

Previous experience: Moderately experienced

Pseudonym: "SGD"

Gender: Man

Home state: Indiana

Previous experience: Slightly experienced

[Candidate pool information]

Here is some information about the average performance of different players in the practice round to help inform your selection decisions:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30
- Average score of men in the practice round: 20.0/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30

[Candidate pool comprehension checks]

Here is some information about the average performance of different players in the practice round to help inform your selection decisions:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30
- Average score of men in the practice round: 20.0/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30

What was the overall average score in the practice round?

Here is some information about the average performance of different players in the practice round to help inform your selection decisions:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30
- Average score of men in the practice round: 20.0/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30

For which groups do you have the average practice round score (check all that apply)?

☐ Men and women

☐ Players from PA and CA

☐ "Not experienced at all" and "Moderately experienced"

[Finalist selection – Control Condition]

Here are the profiles of 10 candidates for you to review. Please take some time to carefully evaluate each of their profiles.

Once you have evaluated each player, please select the 3 players you'd like to designate as finalists for your team.

Candidate pool information:

- Average score in the practice round overall: 19.0/30
- Average score of women in the practice round: 19.0/30
- Average score of men in the practice round: 20.0/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30

[Filler task before the final selection]

Please read the following responses carefully. How would you rank the following responses to the interview question **'What's your biggest weakness?'** from strongest (1) to weakest (4)?

"I can be pretty relentless about high standards. I care a lot about the quality of my work and the team's work, and sometimes that means I spend extra time polishing details or asking follow-up questions others might let go. I've learned to balance that by distinguishing between situations where 'perfect' matters and situations where 'good and on time' is better. I now intentionally ask, 'What level of fidelity is needed here?' so my high standards support outcomes without slowing progress."

"My biggest weakness is that I can be overly self-critical. Even when I've delivered strong results, I tend to focus on what I could have done better, which can sometimes sap my confidence or slow me down when I'm moving on to the next task. Over the last couple of years, I've been working on this by setting clearer success criteria up front and pausing to recognize wins before immediately shifting to improvement. It's still a work in progress, but I've noticed it helps me stay motivated and keeps my perspective more balanced."

"I'd say my biggest weakness is that I'm always trying to improve in multiple areas at once. Like anyone, I have things I'm working on, whether that's communication, prioritization, or time management. I try to regularly reflect on what's working well and where I can get better, and I'm always open to feedback. I see weaknesses as ongoing growth opportunities rather than fixed traits."

"I sometimes get overly excited about new ideas. When I encounter a new tool, strategy, or project direction, I can quickly start brainstorming possibilities and thinking several steps ahead. The upside is that I generate a lot of creative options; the downside is that I have to be careful not to overwhelm others or lose sight of immediate priorities. I've learned to channel that energy by parking ideas in a 'future ideas' list and aligning first on what problem we're solving right now."

[Final selection]

Next, you will continue to evaluate the finalists you just selected and **select the one you would like to join your team.**

As a reminder, here are your two existing team members:

Your team

Pseudonym: "AP"

Gender: Man

Home state: California

Previous experience: Not experienced at all

Pseudonym: "ps"

Below is the profile of the candidate you selected as the final team member.

Pseudonym: "J.R"

Gender: Man

Home state: Massachusetts

Previous experience: Moderately experienced

How many points (out of 10) do you think this candidate will earn on each of the games? After your candidate has played these games, we will compare your prediction to their actual score. You will earn \$0.05 for each accurate prediction you make, for a total of up to \$0.15 across the three games.

Math Game

Angles Game

Trivia Game

[Inferred organizational values]

Please rate the extent to which you agree or disagree with each of the following statements:

When making my candidate selection decisions, I considered whether the organization that developed this hiring task would value including a woman on the final team of hires.

[illegible]

When making my candidate selection decisions, I considered how my choices would align with the values of the organization that developed this hiring task.

[illegible]

[Demographics]

Please complete the following demographic information.

How old are you?

 years old

What is your gender?

- ☐ Man
- ☐ Woman
- ☐ Non-binary
- ☐ Another gender not listed here

What is your racial or ethnic background and heritage? Please check all that apply.

- ☐ Black/African American
- ☐ White
- ☐ East Asian
- ☐ South Asian
- ☐ Southeast Asian
- ☐ Hispanic/Latinx
- ☐ Native American/Native Alaskan
- ☐ Native Hawaiian/Pacific Islander
- ☐ Not listed (please specify)

[Political Orientation]

Here is a seven-point scale on which the political views that people might hold are arranged from extremely liberal to extremely conservative. Where would you place yourself on this scale?

☐ Extremely liberal

☐ Liberal

☐ Slightly liberal

☐ Moderate; middle of the road

☐ Slightly conservative

☐ Conservative

☐ Extremely conservative

General speaking, do you usually think of yourself as a Democrat, a Republican, or an independent?

☐ Republican

☐ Democrat

☐ Independent

Do you think of yourself as closer to the Republican Party or to the Democratic Party

☐ Closer to the Republican Party

☐ Closer to the Democratic Party

☐ Neither

Experiment 2b

The materials for Experiment 2b are identical to Experiment 1b.

Experiment S1a

The materials for Experiment S1a are identical to Experiment 1a, except they do not include any questions on mediators. I.e., they omit the screens: [Perceptions of social norms], [Inferred organizational values], [Perceptions of fairness of the process], [Reactance].

Experiment S1b

The materials for Experiment S1b are identical to Experiment 1b, except they do not include any questions on mediators. I.e., they omit the screens: [Perceptions of social norms], [Inferred organizational values], [Perceptions of fairness of the process], [Reactance].

Experiment S2a

The instructions for Experiment S2a are the same as for Experiment 1a, with three exceptions:

- Information on candidates is different (here we include candidate practice round scores on all candidate profiles).
- Information on candidate aggregate pool performance is different.
- We add an additional set of questions on political orientation.

Instead of repeating all instructions, we only include below screens that differ from Experiment 1a. As such, we do not include instructions screens and comprehension check screens that precede the existing team members screen. We also exclude screens describing mediator questions and demographics.

[Existing team]

Before you pick finalists to round out your team, we want to introduce you to your team's two existing members. Recall that each team will have three players and you will be choosing finalists to fill the only remaining spot on your team of three.

In a moment, we will present the profiles of 10 candidates. We will ask you to select 3 finalists from this pool for your team.

[Finalist selection— Shortlist Quota Condition]

Here are the profiles of 10 candidates for you to review. Please take some time to carefully evaluate each of their profiles.

Once you have evaluated each player, please select the 3 players you'd like to designate as finalists for your team.

At least 1 of the 3 finalists you select must be a woman.

Candidate pool information:

- Average score in the practice round overall: 19.1/30
- Average score of women in the practice round overall: 18.6/30
- Average score of men in the practice round overall: 19.7/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30
- Average score in the practice Math game overall: 7.9/10
- Average score in the practice Angles game overall: 6.5/10
- Average score in the practice Trivia game overall: 4.8/10

[Political Orientation]

Here is a seven-point scale on which the political views that people might hold are arranged from extremely liberal to extremely conservative. Where would you place yourself on this scale?

☐ Extremely liberal

☐ Liberal

☐ Slightly liberal

☐ Moderate; middle of the road

☐ Slightly conservative

☐ Conservative

☐ Extremely conservative

General speaking, do you usually think of yourself as a Democrat, a Republican, or an independent?

☐ Republican

☐ Democrat

☐ Independent

Do you think of yourself as closer to the Republican Party or to the Democratic Party

☐ Closer to the Republican Party

☐ Closer to the Democratic Party

☐ Neither

Experiment S2b

The instructions for Experiment S2a are the same as for Experiment 1a, with three exceptions:

- Information on candidates is different (here we include candidate practice round scores on all candidate profiles).
- Information on candidate aggregate pool performance is different.
- We add an additional set of questions on political orientation.

Instead of repeating all instructions, we only include below screens that differ from Experiment 1a. As such, we do not include instructions screens and comprehension check screens that precede the existing team members screen. We also exclude screens describing mediator questions and demographics.

[Existing team]

Before you pick finalists to round out your team, we want to introduce you to your team's two existing members. Recall that each team will have three players and you will be choosing finalists to fill the only remaining spot on your team of three.

In a moment, we will present the profiles of 10 candidates. We will ask you to select 3 finalists from this pool for your team.

Your team

Pseudonym: "RC"

Gender: Man

Home state: Ohio

Previous experience: Slightly experienced

Practice Math Game Score: 9/10

Practice Angles Game Score: 5/10

Practice Trivia Game Score: 3/10

Pseudonym: "IH"

Gender: Man

Home state: Illinois

Previous experience: Not experienced at all

Practice Math Game Score: 4/10

Practice Angles Game Score: 8/10

Practice Trivia Game Score: 3/10

[Candidate pool information]

Here is some information about the average performance of different players in the practice round to help inform your selection decisions:

- Average score in the practice round overall: 19.1/30
- Average score of women in the practice round overall: 18.6/30
- Average score of men in the practice round overall: 19.7/30
- Average score of players who report being "Not experienced at all" at games in the practice round: 17.0/30
- Average score of players who report being "Moderately experienced" at games in the practice round: 17.5/30
- Average score in the practice Math game overall: 7.9/10
- Average score in the practice Angles game overall: 6.5/10
- Average score in the practice Trivia game overall: 4.8/10
